1 Introduction and Background

Essex Company, LLC (Essex), a subsidiary of Patriot Hydro, LLC, is the Licensee, owner, and operator of the Lawrence Hydroelectric Project (FERC No. 2800) (Project or Lawrence Project). The Project was licensed by the Federal Energy Regulatory Commission (FERC or Commission) on December 4, 1978 (with an effective date of December 1, 1978), and the license expires on November 30, 2028. The Lawrence Project is located on the Merrimack River in the City of Lawrence in Essex County, Massachusetts.

The Project is currently licensed by the Commission under the authority granted to FERC by Congress through the Federal Power Act (FPA), 16 United States Code (USC) §791(a), et seq., to license and oversee the construction and operation of non-federal hydroelectric projects on jurisdictional waters and/or federal lands. In accordance with FERC's regulations at 18 Code of Federal Regulations (CFR) §16.9(b), Essex must file an application for a new license for the Project on or before November 30, 2026. Accordingly, Essex is pursuing a new license for the Project pursuant to the Commission's Integrated Licensing Process (ILP), as described at 18 CFR Part 5 of the Commission's regulations.

Essex filed a Pre-Application Document (PAD) and associated Notice of Intent (NOI) with the Commission on June 16, 2023, the Proposed Study Plan (PSP) on November 28, 2023, and the Revised Study Plan (RSP) on April 10, 2024. The National Environmental Policy Act of 1969 (NEPA), the Commission's regulations, and other applicable statutes require the Commission to independently evaluate the environmental effects of issuing new licenses for the Project, and to consider reasonable alternatives to relicensing. The Commission expressed its intent to prepare an Environmental Assessment (EA) that describes and evaluates the site-specific and cumulative potential effects (if any) of issuing the new license, as well as potential alternatives to relicensing. The EA is being supported by a scoping process to identify issues, concerns, and opportunities for resource enhancement associated with the proposed action. Accordingly, the Commission issued Scoping Document 1 (SD1) for the Project on August 15, 2023. SD1 was intended to advise resource agencies, Indian tribes, non-Governmental Organizations (NGOs), and other stakeholders as to the proposed scope of the EA and to seek additional information pertinent to the Commission's analysis. As provided in 18 CFR §5.8(a) and §5.18(b), the Commission issued a notice of commencement of the relicensing proceeding concomitant with SD1. The Commission's August 15, 2023 SD1 and November 28, 2023 Scoping Document 2 (SD2) identified a variety of aquatic resource issues to be analyzed in the EA for the Project relicensing.

The Commission and MADEP subsequently submitted formal requests related to project effects on water quality, as shown in Table 1-1.

Table 1–1. Water Quality Study Requests

Requestor	Requested Study	Date
FERC	Water Quality Study (FERC Schedule B Study Requests)	October 13, 2023
MADEP	Water Quality Study (MADEP Attachment A)	October 16, 2023

FERC SPD recommendations incorporated into the RSP include relocation of the mid-canal monitoring stations in both the North and South Canal (Station IDs LH-NC-02 and LH-SC-02) to just upstream of the canal discharge points to continuously monitor DO, water temperature, and pH. The FERC SPD also recommended that Essex place a continuous water quality monitor in the "bypassed reach" at the coordinates identified in the PSP as LH-06 "river reach below dam". The LH-BY-01 station was incorporated into the RSP to satisfy this recommendation to assess water quality within the narrow area which receives flow via the spillway only.

There is limited available water quality data for the Merrimack River in the vicinity of the Project. Previously collected data indicate that DO and temperature in the Merrimack River may occasionally exceed water quality standards in the vicinity of the Project; however, the data are greater than 5 years old, limited spatially and temporally, and do not include data from the North and South Canals and their outlets. MADEP and FERC have identified the need for more comprehensive and current water quality information to evaluate the condition of the potentially affected surface waters relative to water quality standards, and to evaluate the Project effects on water quality.

Project operations have the potential to affect water quality in three identified Assessment Units (MA84A-03, MA84A-04, MA84A-10) relative to existing and designated uses; however, there is insufficient existing information to determine the current water quality status of potentially affected surface waters and the associated effects of Project operations on water quality. The completed water quality study documents the current surface water quality conditions in the vicinity of the Project and documents the effects of Project operations on water quality. The study will assist the participating agencies in identifying measures to avoid, minimize, or mitigate potential water quality effects of Project operations to support the existing and designated uses established in the applicable water quality standards.

2 Goals and Objectives

The goal of this study was to collect sufficient data to understand current water quality conditions at the Project, assess the designated uses for the three Assessment Units (MA84A-03, MA84A-04, MA84A-10) potentially affected by the Project, and assess any effects of Project operations on water quality in the affected Assessment Units. Specifically, this study aimed to collect data throughout a single field season that included the following components:

- Measure dissolved oxygen (DO), water temperature, and pH as a vertical profile, and collect Secchi disk depth at the deepest known spot in the impoundment (LH-IM-04).
- Measure DO, water temperature, and pH at sixteen locations under various river flow, river temperature, and project operating conditions to determine the spatial and temporal effects of project operations on water quality. Monitoring locations included five locations upstream of the Project dam (LH-US-01, LH-IM-01, LH-IM-02, LH-IM-03, and LH-IM-04), one location in the tailrace (LH-TR-01), three locations downstream of the Project dam (LH-DS-01, LH-DS-02, and LH-DS-03), two locations each in both the North and South Canal (LH-NC-01, LH-NC-02, LH-SC-01, and LH-SC-02), and two locations in the Spicket River (LH-SR-01 and LH-SR-02). An additional station was added during the study period in the river reach immediately downstream of Essex Dam (LH-BY-01).
- Collect water samples for laboratory analysis of nutrients and chlorophyll-a conditions upstream of the Project dam.
- Collect water samples to characterize water clarity conditions (i.e., turbidity, total suspended solids, and true color) above and below the dam.
- Evaluate the current macroinvertebrate community at locations upstream and downstream of the Project dam.

3 Study Area

The Lawrence Project works consist of: (1) the 35-foot-high by 900-foot-long gravity Essex Dam of stone masonry construction (also known as the Great Stone Dam), with a five-foot-high pneumatic crest gate system mounted on the spillway crest; (2) a 9.8-mile-long impoundment having a surface area of 655 acres at a normal water elevation of 44.17 feet National Geodetic Vertical Datum of 1929 (NGVD) at the top of the crest gates, and gross storage capacity of approximately 19,900 acre-feet; (3) a powerhouse located at the end of a small forebay adjacent to the south abutment of the Essex Dam, containing two 8.4 megawatt (MW) generating units, and a tailrace channel extending into the Merrimack River channel; (4) fish passage facilities integral with the powerhouse, including a fish elevator and downstream fish bypass, and an eel ladder at the right abutment of the dam; (5) the North Canal, approximately 5,300 feet long by 95 feet wide by 15 feet deep, originating at the north abutment of the dam and paralleling the Merrimack River downstream of the Essex Dam; (6) the South Canal, approximately 2,750 feet long by 35 feet wide by 10 feet deep, originating at the south abutment of the Essex Dam and generally paralleling the Merrimack River downstream of the Essex Dam; (7) a single-circuit, underground/underwater 23.0-kilovolt (kV) transmission line to the Massachusetts Electric Company's Lawrence No. 1 substation; and (8) appurtenant facilities.

The study area includes three hydrologic Assessment Units (MA84A-03, MA84A-04, MA84A-10), specifically the sections of the Merrimack River located immediately upstream of the Essex Dam, the Essex Dam Project development area including the main channel, tailrace, North Canal, South Canal, flow diversion structures, and the Merrimack River immediately below the Project,

as well as the lower Spicket River from where the North Canal discharges into the Spicket River to its confluence with the Merrimack River. AU MA84A-03 is an 8.8-mile reach from the Lowell regional wastewater utility's outfall at Duck Island, Lowell to Essex Dam. AU MA84A-04 is a 10.0-mile reach from the Essex Dam downstream to the confluence of the Merrimack and Little Rivers in Haverhill, Massachusetts. The 3.2-mile reach of the Merrimack River from the Pawtucket Dam in Lowell to the Duck Island outfall is AU MA84A-02 and is upstream of the area of potential project effects on flow and water quality. AU MA84A-10 is a 5.8-mile reach of the Spicket River from the NH border in Methuen to the confluence with the Merrimack River in Lawrence.

4 Methodology

4.1 Overview

The water quality study was conducted consistent with the RSP and additional agency requests over a four-month period from June 2, 2025, through October 1, 2025, documenting water quality conditions in the Project area under a range of flow and operating conditions. Data collection occurred at 16 monitoring locations in the vicinity of the Project. The monitoring locations are presented in Table 4-1 below. During the study, the locations of three monitoring stations were modified due to site conditions that made the intended location of a monitoring station temporarily inaccessible or unrepresentative of the water body. The modified ("alternate") site locations are presented in Table 4-2 below.

Table 4–1. Station Coordinates

Station ID	Dates	Logger Coordinate N	Logger Coordinate W	Logger Deployment Depth (ft)

LH-US-01	6/09/2025 – 6/16/2025	42.64478	-71.29129	4.0

This study included near-continuous water quality monitoring with deployed instruments (Onset Hobo U26-001 DO & temperature logger, Onset Hobo MX2501 pH & temperature logger, and Onset Hobo U20-001 water level logger [used for barometric pressure reference]) at each of the 16 monitoring locations. Vertical profiles of DO and water temperature were collected weekly throughout the four-month study at Monitoring Station LH-IM-04 (the deepest location in the impoundment). A YSI ProDSS multi-parameter water quality data sonde was used for measuring vertical profiles and for quality control (QC) readings to evaluate the calibration and performance of the deployed data loggers. Secchi disk depth was measured concurrently with the water quality profiles at Station LH-IM-04 to assess water clarity in the impoundment. In addition, water samples were collected on five occasions during the study period for laboratory analysis of nutrient and water clarity.

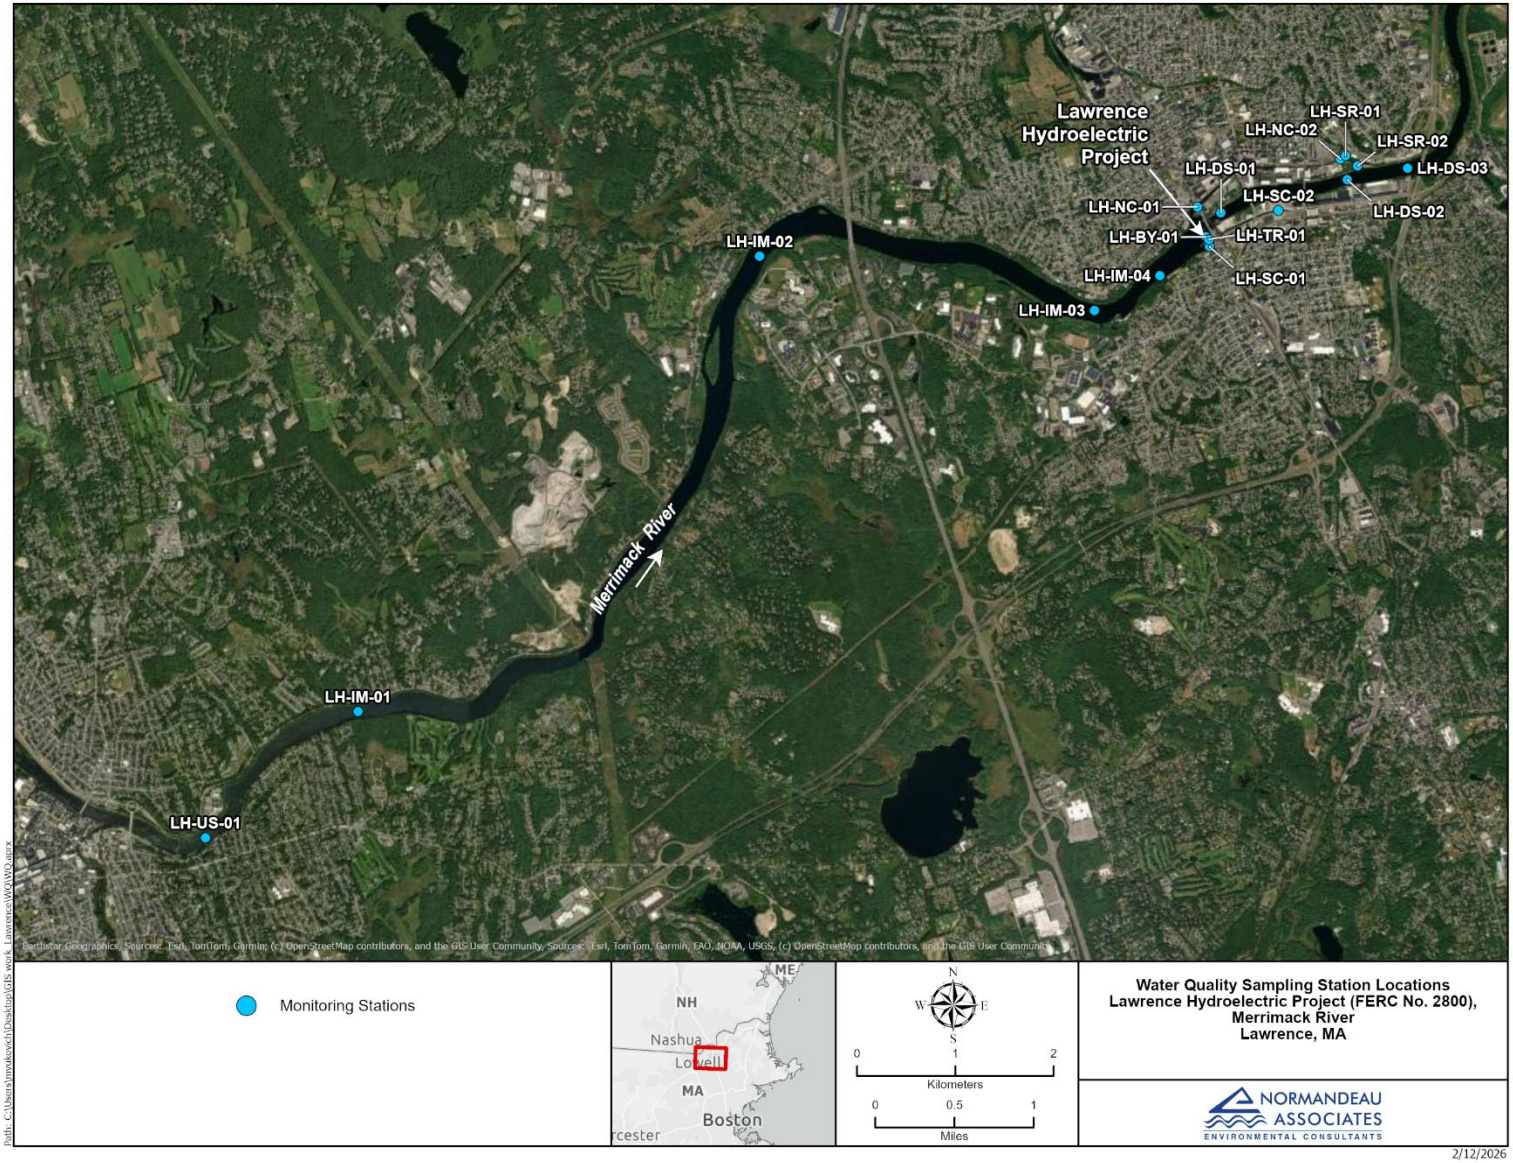

Figure 4-1. Site map of sampling locations.

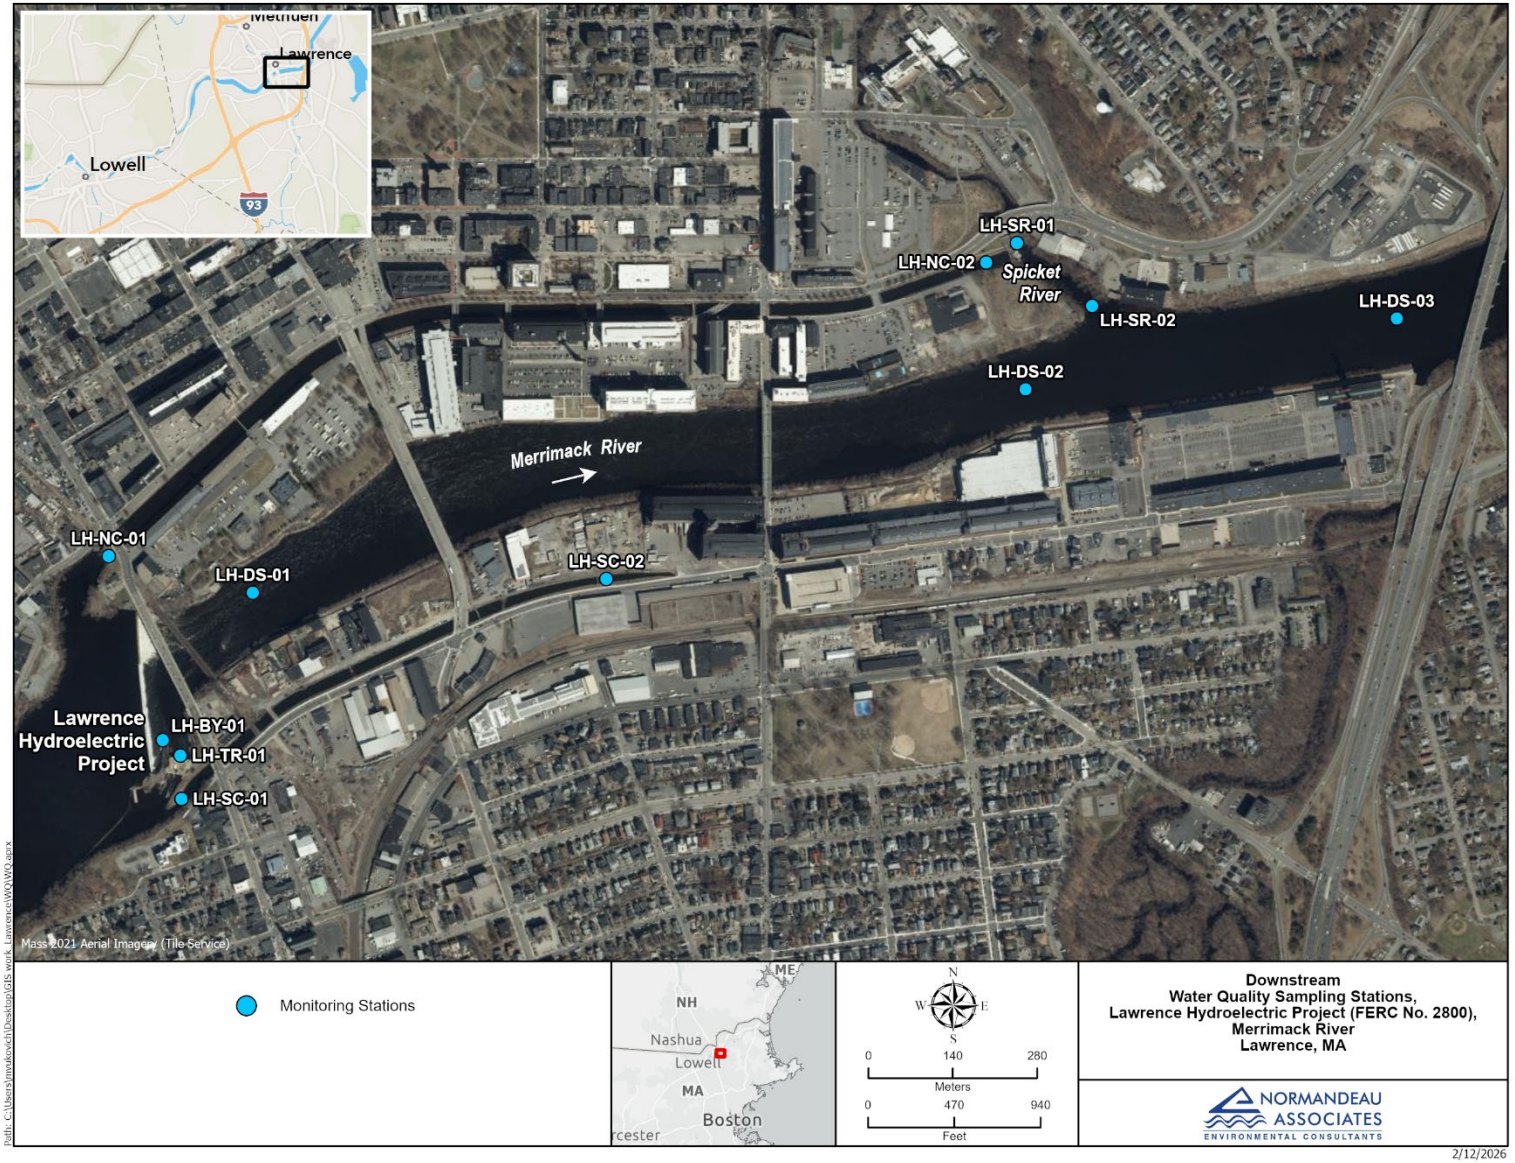

Figure 4-2. Site map of sampling locations (detail 1).

Figure 4-3. Site map of sampling locations (detail 2).

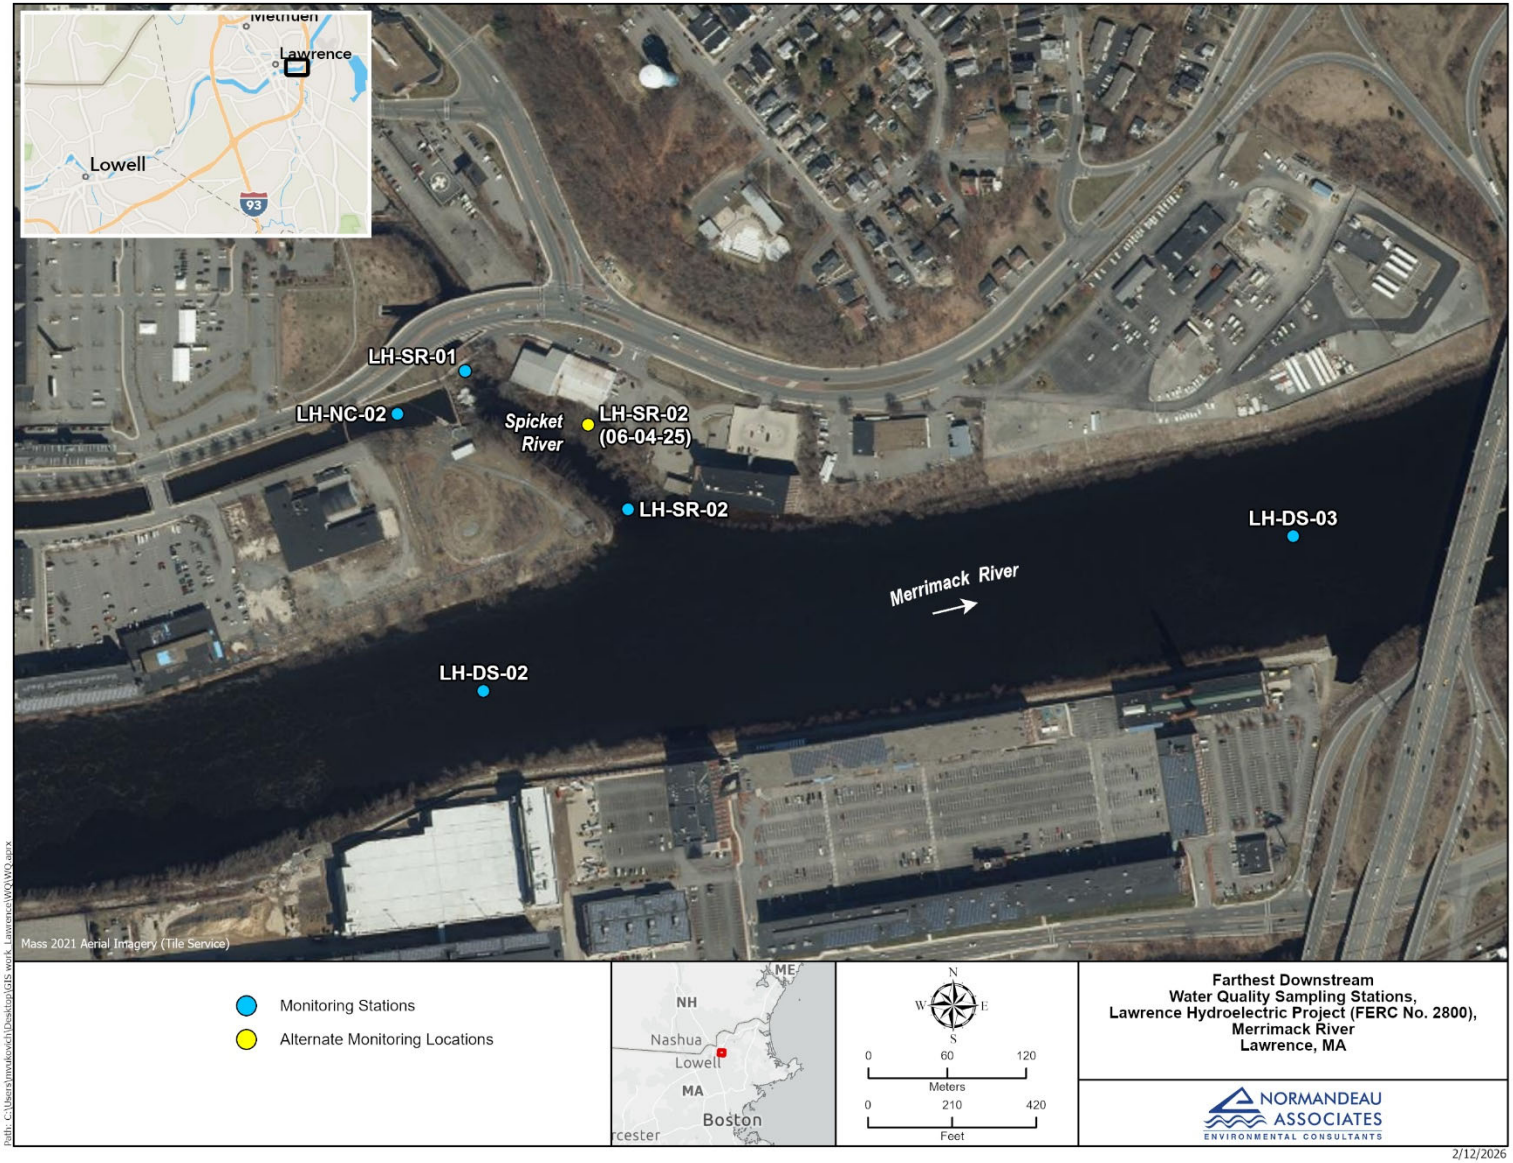

Figure 4-4. Site map of sampling locations (detail 3).

4.2 Continuous Water Quality Data Logging

Continuous logging instruments were deployed at mid-depth at each monitoring location with an anchor and buoy system. Loggers installed at the North and South Canals were deployed from a suspended cable. Deployed instrumentation was set to collect water quality data at 15-minute intervals and remained deployed (with exceptions) for the entirety of the study period of approximately June 2–October 1 (see Table 4-1 for deployment periods at each station). An exception to this was the South Canal stations, as the canal was dewatered for a construction project and therefore loggers were not deployed during the periods of dewatering (loggers not deployed from 6/10/25 to 6/16/25 and 6/18/25 to 8/5/25). Another exception was at LH-SR-01, when the loggers were pulled during week six of the study due to the low water levels in the Spicket River and associated site access and instrument deployment issues (spot measurements continued weekly at LH-SR-01 as an alternative to continuous logging).

Deployed instruments were retrieved weekly to download data and to maintain, clean, and calibrate the instruments. An additional water quality instrument (YSI ProDSS, also used for vertical profiles and assessing thermal stratification) was used for independent calibration checks of the continuously deployed instrumentation as detailed in the QA/QC protocols. Calibration of the deployed loggers occurred weekly using 100% water saturated air for dissolved oxygen. The barometer used for determining oxygen saturation values at calibration and for calculating oxygen saturation values in the data record (i.e., from oxygen concentration values) was a water level pressure logger dry-mounted at the site as an atmospheric pressure reference. Calibration of the additional QC meter was conducted each field day prior to use. If necessary, a second YSI instrument was also used to independently confirm QC readings when there were large differences between instruments or suspect measurements.

4.3 Vertical Profiles of DO and Water Temperature

Water quality measurements taken as a vertical profile through the water column were collected weekly during site visits at the Project impoundment (monitoring station LH-IM-04, impoundment deepest spot). A survey of water depths in the impoundment was completed at the beginning of the study to determine the deepest location in the Lawrence Dam impoundment. Depth measurements with a sonar fish finder were taken at regular intervals along the centerline of the Merrimack River from the buoy line above the dam upstream to determine the deepest impoundment zone in the river. The impoundment deep spot was further refined by returning to the centerline deep spot, then sweeping across the river in a grid pattern making regular depth measurements to locate the deepest accessible point above the dam. The depth was confirmed with a weighted tape measure (confirmed depth = 35 feet) then marked with a GPS position.

A YSI ProDSS multi-parameter water quality sonde was used to measure dissolved oxygen and water temperature as a vertical profile at 0.1 m below the surface, 0.5 -m below the surface, then every 0.5 -m down to 0.1 m above the bottom. Measurements at each depth interval were allowed

to stabilize prior to recording. Prior to use each field day, the YSI ProDSS was calibrated following manufacturer guidelines using the water saturated air method for DO calibration (temperature measurements utilized the default factory calibration). A zero DO calibration was also completed when required for low DO concentrations of less than 4.0 mg/L. Low DO concentrations were determined from the deployed logger or initial readings with the vertical profiler instrument. Vertical profile data were recorded manually on field data sheets.

4.4 Secchi Disk Depth

Secchi disk depth was measured at the Project impoundment deep spot monitoring station (LH-IM-04) concurrent with vertical profiles. An underwater viewer was used to view the Secchi disk. The Secchi disk depth was the average of the visible depth while lowering and raising the disk.

4.5 Water Sample Collection for Laboratory Analysis of Nutrients and Chlorophyll-a

Water samples were collected at three monitoring stations in the project area to characterize nutrient and chlorophyll-*a* conditions immediately above the project impoundment (LH-US-01) and at two stations within the project impoundment (LH-IM-02 and LH-IM-03) and analyzed for total phosphorus (TP), total nitrogen (TN), and chlorophyll-*a*. Samples were collected during five separate sampling events between June and October. TN and TP samples were collected from the near-surface (i.e., 25% of total depth) with a Van Dorn sampler. Chlorophyll-*a* samples were collected as a depth-integrated composite sample for the upper 2 m of the water column. An integrated core sample is collected using weighted tubing to extract an equal volume of water from all depths. All samples were preserved, stored, handled, and delivered to the participating analytical lab according to lab specifications. One field replicate was collected every 10 samples.

4.6 Water Sample Collection for Laboratory Analysis of Turbidity, Total Suspended Solids, and True Color

Water samples were collected at four monitoring stations in the project area to characterize water clarity conditions above and below the dam and samples were analyzed for Turbidity, Total Suspended Solids (TSS), and True Color. Samples were collected during five monthly sampling events between June and October. Samples were collected from the near-surface (i.e., 25% of total depth) with a Van Dorn sampler. Turbidity was measured in the field with a turbidity meter and utilized the same sample water collected for laboratory analysis of TSS and Color. All samples were preserved, stored, handled, and delivered to the participating analytical lab according to lab specifications. One field replicate was collected every 10 samples.

4.7 Quality Assurance/Quality Control (QA/QC) Protocols

Prior to deployment, redeployment, or use for spot measurements, water quality instruments were cleaned, inspected for fouling, damage, or other performance affecting conditions, and calibrated according to manufacturer recommendations and established best practices. A log of calibration data was maintained to establish a project record of instrument performance history. Calibration acceptance criteria are presented in Table 4-3. Calibration information is provided in Appendix A and a summary of calibration checks that failed the QA/QC targets is provided in Tables 5-4 and 5-6. Field replicate samples were collected during the study at a frequency of 1 replicate per every 10 samples. Field replicates were also completed for vertical profile measurements and Secchi disk depth measurements. The field replicates provide a QC assessment of field sampling methods and any potential sampling errors.

Table 4–3. Field Meter Calibration Method, Frequency, and Acceptance Criteria

Parameters	Frequency of Calibration	Calibration Acceptance Criteria
Dissolved Oxygen	Instantaneous readings Prior to each measurement Datasonde Deployments Datasonde must be calibrated before deployment and at least weekly (or more frequently if meter fouling is likely to occur).	Instantaneous readings Record the calibration value in % saturation and after one-minute record the % saturation reading and compare to the calibration value. The dissolved oxygen % saturation reading should be ± 5.0% of dissolved oxygen % saturation calibration value. Datasonde Deployments After the datasonde is calibrated, record the datasonde instantaneous mg/L reading immediately after calibration and the Oxygen Solubility in Water Value based on concurrent water temperature and barometric conditions. The difference between the datasonde instantaneous reading immediately after calibration and the Oxygen Solubility Water Value must be no greater than ± 0.2 mg/L. If the difference is greater, recalibrate. Datasonde Retrieval After removal from water, set up the datasonde so that it is under 100% saturated air conditions. After dissolved oxygen readings have stabilized, record the datasonde instantaneous mg/L reading and the Oxygen Solubility in Water Value based on concurrent water temperature and barometric conditions. The difference between the datasonde instantaneous reading immediately after calibration and the Oxygen Solubility Water Value must be no greater than ±0.5 mg/L. If the datasonde is going to be redeployed, and it hasn't been more than 1 week since the last calibration, recalibrate if the difference is greater than ±0.2 mg/L. If it has been 1 weeks since the last calibration, recalibrate regardless of the difference.
Temperature	Not Applicable	Not Applicable

Parameters	Frequency of Calibration	Calibration Acceptance Criteria
pH	Instantaneous readings Three-point calibration prior to each measurement (4.00, 7.00, and 10.00 calibration standards) Datasonde Deployments Datasonde must be calibrated before deployment and at least weekly (or more frequently if meter fouling is likely to occur).	Instantaneous readings Record calibration slope prior to each measurement. Slope should be between 95% - 105%. If slope is out of range, the meter should be recalibrated. Datasonde Deployments After three-point calibration record the datasonde reading of the standards used. Reading should be ± 0.05 pH units from each calibration standard. If the difference is greater, recalibrate. Datasonde Retrieval Datasonde should measure the standards used in the calibration. Datasonde readings should be ± 0.3 pH units from each calibration standard. If the datasonde is going to be redeployed, and it hasn't been more than 1 week since the last calibration, recalibrate if the difference is greater than ± 0.3 pH units. If it has been 1 week since the last calibration, recalibrate regardless of the difference.

Instrument performance was evaluated using side-by-side QC readings between deployed -m and a handheld meter (i.e. the YSI ProDSS used for vertical profiles). The acceptance criteria for simultaneous measurement differences between instruments are presented in Table 4-4, below. A summary table that includes the relative percent difference and absolute difference values from side-by-side QC reading data pairs and data pairs that fail the QA/QC acceptance criteria is presented in Appendix A.

Table 4–4. Data QC Acceptance Criteria

Parameters	Frequency of Measurement Checks*	Acceptance Criteria (i.e., maximum difference between the handheld and datasonde measurements)* RPD – Relative Percent Difference ABS – Absolute Difference
Dissolved Oxygen	Handheld measurements should be taken at the time of datalogger deployment, once a week throughout the deployment and at the time the datalogger is removed. Handheld measurements should be taken as close as possible to the location of the datalogger.	RPD between handheld measurement and datalogger should be ≤ 10%. If RPD is > 10% the absolute value of the difference between the handheld measurement and the datalogger measurement should be ≤ 0.4 mg/l or ≤ 4% saturation.
Temperature	Same as above	RPD between handheld measurement and datalogger should be ≤ 10%. If RPD is > 10% the absolute value of the difference between the handheld measurement and the datalogger measurement should be ≤ 0.5 °C.

Parameters	Frequency of Measurement Checks*	Acceptance Criteria (i.e., maximum difference between the handheld and datasonde measurements)* RPD – Relative Percent Difference ABS – Absolute Difference
pH	Same as above	The absolute value of the difference between the handheld measurement and the datalogger measurement should be ≤ 0.3 pH units
Specific Conductance	Same as above	± 5 µS/cm or ± 3% of the measured value, whichever is greater

*Adjacent measurements with the handheld meter are taken at same location and depth as the datasonde.
** The relative percent difference (RPD) is equal to the following:

$$RPD = \frac{|x_1 - x_2|}{\frac{x_1 + x_2}{2}} \times 100\%$$

where x_1 is the original sample concentration, and x_2 is the replicate sample concentration

The continuous monitor sonde data were stored electronically in the data logger and downloaded in the field to a handheld device (for pH data) and laptop computer (for DO data). All data downloaded to the handheld device and computer were transferred to the Normandeau computer network and subsequently formatted and quality controlled. Field data recorded on data sheets were processed, quality controlled, and stored with the other project data. Data analysis was completed using software such as Microsoft Excel, Aeronautical Reconnaissance Coverage Geographic Information System (ArcGIS), and R language programming software. All project data is stored on the Normandeau network which is backed up nightly.

4.8 Flow and Operations Data

Operations data for the Project, including flows through the various Project components and power generation were developed by Patriot and are provided in this report. Flow records were developed for the study period and include inflow to the Lawrence Dam impoundment, outflow through the turbines and into the Project tailrace, fish passage facility flows, estimated spill flows, spillway flow to the river reach immediately downstream of Essex Dam, and flows through the North and South Canals. Inflow was developed for the Project impoundment from the 15-minute data obtained from the nearest USGS gage in the watershed (USGS 01100000 MERRIMACK RIVER BL CONCORD RIVER AT LOWELL, MA[1]), prorated by the ratio of drainage areas (4,674 mi^2/4,635 mi^2 = 1.01). Turbine outflow was determined from power output of individual turbine units and established power-flow relationships. Fish passage flows and fish bypass flows are gate-controlled and assumed steady during the applicable upstream and downstream fish passage

1 https://waterdata.usgs.gov/monitoring-location/01100000/#parameterCode=00060&period=P7D&showMedian=false

seasons. Canal flows result primarily from leakage and are assumed steady. Spill is calculated as the difference between inflow and the sum of outflows.

4.9 Benthic Macroinvertebrate Sampling and Analysis

A 500-m reach was identified at locations upstream and downstream of the Project in consultation with MADEP on May 30, 2025 (Figure 4-5). The upstream station was located above the Lowell City Wastewater Treatment Plant at the upper reaches of the Project boundary (Figure 4-6). The downstream station was located approximately 1,400 -m downstream of the Essex Dam and was bisected by the confluence with the Spicket River and North Canal (Figure 4-7).

4.9.1 Macroinvertebrate Sampling

As described in the RSP, benthic macroinvertebrate (BMI) sample collection was conducted following methods identified in the Large River Bioassessment Protocol (LR-BP) for Benthic Macroinvertebrate Sampling as described in the USEPA guidance document Concepts and Approaches for the Bioassessment of Non-wadeable Streams and Rivers (Flotemersch et al. 2006).

Per Flotemersch et al. (2006), within each 500-m reach, a total of six transects were evenly spaced. Transect 1, where sampling was initiated, was established at the downstream extent of the reach with the remaining five transects established at 100-m intervals continuing upstream (i.e., six total transects per reach). A sampling zone was established five -m upstream and downstream from where each transect intersected with the riverbank (i.e., 10 -m along the shoreline). This shoreline sample zone was extended out into the river to the point where river depth exceeded one meter, defining the zone where macroinvertebrates were collected. Six sweeps, each 0.5-m in length, were collected within each sampling zone using a D-frame net (500-µm mesh) and each sweep covered approximately 0.15 m^2 of substrate (i.e., six sweeps cover an area of 0.9 m^2). The six sweeps were proportionately allocated based on available habitat within the sample zone, with slight adjustments at some transects to account for field conditions, such as access and safety considerations. Each transect had two sampling zones (north and south bank) and collections from the entire 500-m reach (i.e. all net collections from all transect sampling zones) were composited into a single sample. This resulted in a sample composed of collections from 12 separate zones throughout the 500-m reach (total of ~12 m^2).

All net collections for a 500-m reach were composited into a 500-µm sieve bucket and allowed to drain before washing and preservation. Larger objects (i.e. rocks and woody debris) were removed after rinsing into the sieve bucket and scrubbing or brushing to remove any visible macroinvertebrates. Following removal of larger objects and removal of fine sediment through the sieve bucket, samples were transferred to an externally and internally labeled container and preserved with ethanol (70% final concentration).

4.9.2 Macroinvertebrate Sorting, Identification, and Metric Analysis

Macroinvertebrate samples were sent to the Normandeau benthic taxonomy laboratory in Stowe, Pennsylvania where taxonomists sorted, identified, and enumerated each sample. Each sample was split into a 28-part grid with randomly selected squares sorted and identified until a minimum of 500 specimens were enumerated (each grid section selected was sorted and identified in its entirety regardless of when the 500 individual minimum was reached). Sorted organisms were analyzed using stereo-zoom and compound microscopes then identified and enumerated to the lowest practical taxon, generally genus and species, dependent on their age and condition using published taxonomic keys.

Flotemersch et al. (2006) provide a list of metrics by which to evaluate (1) richness and diversity, (2) composition and evenness, (3) pollution intolerance, and (4) functional feeding groups. Metrics selected to represent each of the numbered categories to be evaluated included:

1) **Richness and Diversity:**
   - ***Taxa Richness***. The count of unique taxa in a sample (to genus level or finer). Barbour et al. (1999) defines this as a measure of overall variety of the macroinvertebrate assemblage and is predicted to generally decrease in response to increasing disturbance.
   - ***EPT (Ephemeroptera, Plecoptera, Trichoptera) Richness****:* The number of taxa in the orders Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies). Similar to taxa richness, this metric is predicted to decrease with increased habitat disturbance (Barbour et al. 1999).
   - ***Shannon Diversity***: This metric compares the distribution of individuals among all taxa present in a sample. Shannon Diversity (H') is calculated as $H' = \Sigma\, p_i \ln p_i$, where p_i is the proportion of the total number of individuals occurring in taxon i. Maximum diversity is obtained when numbers of individuals are equally distributed among taxa. A value near zero indicates community dominance by a small number of taxa. Higher values indicate that the numbers of individuals are evenly distributed.

2) **Composition and Evenness:**
   - ***Percent Contribution of Dominant Taxon***. Individuals in the most numerous unique taxon (genus level) as a percentage of all individuals within a sample.

3) **Pollution Intolerance:**
   - ***Hilsenhoff Biotic Index***. A weighted average of the tolerance values of all taxa present. Organisms are assigned a tolerance value from 0 to 10 indicating their sensitivity to organic pollutants (0 being most sensitive, 10 being most tolerant). HBI is calculated as:

     $$HBI = (\Sigma n_i \times a_i)/N$$

     Where:

n = number of specimens in taxon i
a = tolerance value of taxon i
N = total number of specimens in sample

4) **Functional Feeding Groups**:
   - ***Percent collector-gatherer individuals.*** The number of unique taxa feeding on particles from benthic substrates and available detritus. According to Barbour et al. (1999), taxa classified under this category tend to be generalists (as opposed to specialized feeders such as scrapers, shredders, etc.) and can be more tolerant of disturbance.

Scores for each metric were generated for the upstream and downstream BMI sampling reaches. Per the request by MADEP, where possible, all odonates were identified to species.

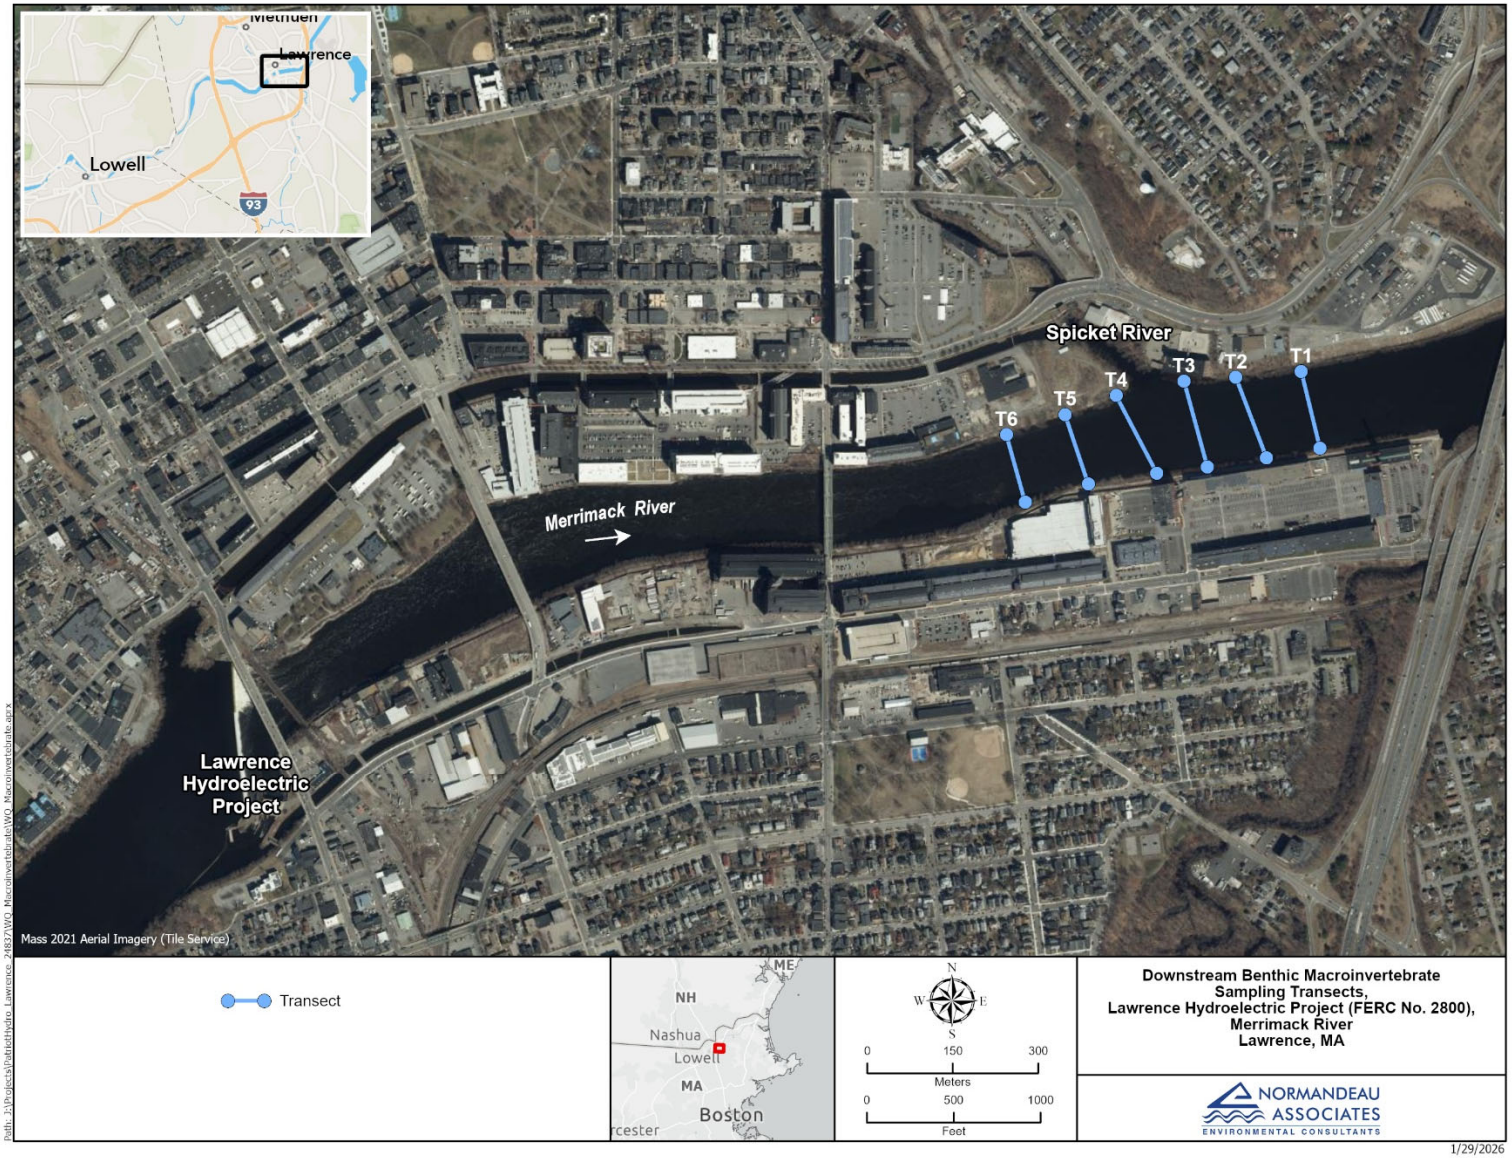

Figure 4-7. Downstream transects for macroinvertebrate collection, August 20th, 2025.

5 Results

The results of the water quality study are presented below and include continuous monitoring data, vertical profiles, lab data, and Secchi disk depth, as well as supplemental spot measurements with mobile water quality data sondes. Use codes were assigned to continuous monitoring data to account for instrument performance issues such as fouling, environmental interferences, instrument drift, and suspect data. Use code 1 was assigned to valid data usable for analytical tasks. Use code 2 was assigned to data points when the logger was out of the water for weekly downloads and service and therefore not valid data. Use code 3 was used for periods where the loggers were deployed but the data collected were determined to be invalid including periods of dewatering, or logger failure. Use code 4 was assigned when there was failure of a QC check and/or obvious data anomaly, typically due to biofouling. Data points assigned use code 1 are presented in all figures and tables, use codes 2 and 3 are omitted from the tables, figures, and statistics as they are invalid readings. Data assigned use code 4 are presented in the figures as it is informative and conveys useful information but are omitted from statistical summaries and site records due to failing QC criteria. Data assigned use code 4 likely include some period of valid data, as biofouling and instrument drift occur gradually, however the exact timing of when an instrument exceeded QC criteria cannot be determined.

5.1 Continuous Water Quality Data Sonde Measurements

Each of the 15 proposed monitoring stations from the RSP plus an additional monitoring station at the river reach immediately downstream of Essex Dam were instrumented with continuous monitoring water quality data loggers. The deployment period was generally from June 1 through September 30, 2025, but varied slightly depending on the installation date of each logger. The data loggers installed in the river reach immediately downstream of Essex Dam (LH-BY-01) were deployed later, beginning July 1, as this station was requested by the participating agencies after the study had commenced on June 1. Additionally, the loggers were removed from the South Canal for much of June and July when the South Canal was dewatered for construction/maintenance activities. The loggers were also removed early in the study on July 8 from the Spicket River station LH-SR-01, when low water conditions, site access challenges, safety issues, and lack of viable continuous monitoring deployment options necessitated abandoning this station. Weekly spot measurements continued at LH-SR-01 in lieu of continuous monitoring. Table 5-1 summarizes logger deployment information at each station including the number of valid (use code 1) readings collected during the study.

Table 5-1. Deployment Periods and Number of Valid Data Points Collected by Station

Continuous Monitoring Station	DO/Temp Deployed	DO/Temp Retrieved	No. of Valid DO/Temp Data Points	pH Deployed	pH Retrieved	No. of Valid pH Data Points
LH-US-1	6/3/2025	9/29/2025	10,571	6/3/2025	9/29/2025	9,432
LH-IM-01	6/3/2025	9/29/2025	10,620	6/3/2025	9/29/2025	8,798

Continuous Monitoring Station	DO/Temp Deployed	DO/Temp Retrieved	No. of Valid DO/Temp Data Points	pH Deployed	pH Retrieved	No. of Valid pH Data Points
LH-IM-02	6/3/2025	9/29/2025	7,057	6/3/2025	9/29/2025	6,982
LH-IM-03	6/3/2025	9/29/2025	8,128	6/3/2025	9/29/2025	6,482

5.1.1 Water Temperature

The objective of continuous temperature monitoring was to collect baseline information on water temperature in and around the Project area and assess the effects of the Project on water temperatures under a range of flow and operating conditions. Water temperatures were monitored successfully at each of the 16 water quality monitoring stations for all or some portion of the study period, as summarized in Table 5-1, and included periods of variable flows and power generation. Water temperatures varied from 16.06 to 30.22 °C among all stations during the study, with a global average temperature of approximately 23 °C. Water temperatures were generally comparable between stations throughout the study period and there were similar temperature values, daily ranges, and trends amongst stations as presented in Table 5-2 and Figures 5-1 through 5-17.

Daily temperature ranges were variable in time and between stations and were associated with flows, water depth, and reach type. Daily water temperature fluctuations were lowest on the rising limb of event flows and at high flows and greatest at low flows (Figure 5-17). Daily temperature variation was also positively associated with shallower water depths/monitoring depths with shallow riverine reaches generally showing greater daily temperature ranges than stations in deeper impounded water. Fluctuations in daily temperature in the Merrimack River were greatest at Stations LH-US-01 and LH-IM-01, which were located upstream of the project in a shallow riverine reach (LH-US-01, Figure 5-1) and near the head of the impoundment (LH-IM-01, Figure 5-2), respectively. Daily temperature ranges were often on the order of 1-2 °C at these two stations, while stations lower in the impoundment (LH-IM-02, LH-IM-03, LH-IM-04), often had daily temperature variations of 0.5 °C or less, most likely due to the deeper deployment depths at those stations. Stations downstream of the dam (LH-DS-01, LH-DS-02, LH-DS-03) also exhibited diel temperature variations, with greater temperature variability at stations LH-DS-02 (Figure 5-9) and

LH-DS-03 (Figure 5-10) compared to LH-DS-01 (Figure 5-8), which was located immediately below the dam.

Water temperatures and river flows followed typical seasonal patterns during the 2025 study. At the start of the study in June flows in the Merrimack River were high with flows generally greater than 10,000 cfs and as high as 25,000 cfs through June 25 (Figure 5-17). Water temperatures remained in the middle-upper teens °C during the high flow period and then rose to the mid-20s °C by June 26, while flows decreased to less than 5,000 cfs in the same period. Temperatures then remained in the mid- to upper-20s °C from June 25 to Aug 19, corresponding with flows of approximately 1,000–2,000 cfs. A gradual cooling trend began at the end of August and extended through September with temperatures by the end of the study cooling to about 20 °C. Water temperatures reached three distinct peaks during the study with values approaching or exceeding the 28.3°C water quality standard (discussed further in section 5.4) at multiple stations in the third week of July, the last week of July, and the second week of August. Flows in the Merrimack River reached a seasonal minimum in September with average flows frequently less than 1,000 cfs outside of two precipitation events that resulted in minor but temporary increases in flows above 2,000–3,000 cfs. Maximum water temperatures were mostly associated with low river flows of less than 3,000 cfs, although the lowest flows occurred in September after water temperatures had peaked and began to cool for the season.

While temperatures in the main channel areas of the Merrimack River and the canals were comparable throughout the study, temperatures in the river reach immediately downstream of Essex Dam and the Spicket River were more variable. The station immediately downstream of the dam, LH-BY-01, was characterized by significant increases and decreases in temperature over short periods of time during the month of July and included temperature spikes outside of the expected water temperature range (Figure 5-7, flagged as use code 4). The documented pronounced temperature changes were associated with changes in turbine outflows to the tailrace and the resulting changes in water level in the river reach immediately downstream of Essex Dam at the deployed logger station. It is likely that when turbine outflows were high, the deployed logger was submerged and within free-flowing water influenced by the tailrace outflows. In contrast, when turbine outflows dropped, water levels in the vicinity of the monitoring station in the river reach immediately downstream of Essex Dam dropped and the deployed logger was susceptible to dewatering and/or a shallow water environment characterized by exaggerated heating and cooling cycles (Figure 5-7). After July 28, temperatures at the station in the river reach immediately downstream of Essex Dam stabilized and were comparable to other stations through the end of the study. The logger placement changed several times at LH-BY-01 depending on site accessibility (this site was only accessible on foot) which was limited by water levels at the time of logger deployment. The more stable water temperatures recorded in August and September likely represent logger placements closer to the thalweg of the river reach immediately downstream of Essex Dam where sufficient water was available for monitoring, regardless of project

operations, while earlier placements may have been off the thalweg and therefore subject to dewatering.

Temperatures in the Spicket River above the confluence with the North Canal (station LH-SR-01) were more variable than in the Merrimack River, although data are limited at that station due to abandoning continuous monitoring after mid-July (due to low water conditions and associated lack of viable deployment locations), as presented in Figure 5-15. The Spicket River at this station was shallow and had low flows through much of the study period. The Spicket River station below the confluence with the North Canal (LH-SR-02) had temperature patterns that were less variable than at LH-SR-01 and more similar to the Merrimack River stations, as presented in figure 5-16. Station LH-SR-02 was located in a reach of the Spicket River that was subject to backwater effects from the Merrimack River and did not experience the low water conditions documented at LH-SR-01.

Table 5-2. Summary of Continuous Monitoring Water Temperature (℃)

Continuous Monitoring Station	Temperature (℃)			
	Min	Max	Mean	Median
LH-US-1	16.52	28.42	23.87	24.80
LH-IM-01	16.48	28.58	23.44	23.92
LH-IM-02	16.40	27.86	22.66	21.84
LH-IM-03	16.52	28.50	23.21	23.18
LH-IM-04	16.58	26.90	23.55	23.82
LH-TR-01	16.10	28.22	23.72	24.50
LH-BY-01	19.38	28.40	23.76	23.75
LH-DS-01	19.32	28.22	24.45	25.16
LH-DS-02	17.18	28.26	23.82	24.64
LH-DS-03	17.16	28.72	24.16	25.12
LH-NC-01	16.10	29.78	24.00	24.80
LH-NC-02	16.30	30.22	23.26	22.60

5.1.2 Dissolved Oxygen

The objective of continuous dissolved oxygen monitoring was to collect baseline information on dissolved oxygen concentration and saturation in and around the Project area and assess the effects of the Project on DO levels under a range of flow, temperature, and operating conditions. Dissolved oxygen was monitored successfully at each of the 16 water quality monitoring stations for all or some portion of the study period, as summarized in Table 5-1, and included periods of variable flows, temperatures, and power generation. The results of the continuous DO monitoring are presented in Table 5-3 and Figures 5-18 through 5-51. DO was generally measured at high levels among all stations and throughout the study period with few exceedances of the 5 mg/L DO water quality standard (discussed in Section 5.4). Low DO events were spatially limited and temporary. Multiple apparent low DO events were determined to be invalid data (use code 4) due to biofouling on the loggers and accumulation of organic material between calibration events; the invalid data are presented in figures for informational purposes but are omitted from station statistics. DO concentration varied from 3.45 to 14.41 mg/L among all stations during the study, with a global average DO concentration of about 8.5 mg/L. Dissolved oxygen saturation varied from 42.59 to 189.61 % and averaged about 99.4 %, while daily average dissolved oxygen saturation varied from 60.95 to 156.58 % and averaged about 99.8% among all stations. DO levels were variable over the course of the study period and between stations and exhibited seasonal variations as well as short term trends and daily patterns as presented in Figures 5-34 and 5-51.

Water temperatures and river flows followed typical seasonal patterns during the 2025 study, as discussed in 5.1.1, with high flows early in the study in June and low flows from July through the end of the study in September. In June, with flows in the Merrimack River generally greater than 10,000 cfs, DO was uniformly high across all stations and was positively associated with flow, increasing with higher flow/decreasing temperature, and decreasing with lower flow/increasing temperature (Figures 5-17, 5-34, and 5-51). At high flows, DO was relatively comparable between stations and daily variations were minimal in the Merrimack River, while daily variations were greater in the lower North Canal and Spicket River. Flows started receding after June 20 and by the start of July were below 5,000 cfs in the Merrimack River at Lawrence. During this flow recession period DO became more variable between stations and showed more variability during diel cycles. From the middle of July through the end of the study, coinciding with a prolonged low flow period, DO was highly variable between stations and diel DO cycles were pronounced at nearly all stations, increasing during daylight hours and decreasing during the evening.

Upstream of the Project impoundment at Station LH-US-01, DO conditions were relatively stable and well above the state standard of 5 mg/L throughout the study period and DO saturation was consistently between 80 and 120% with pronounced diel DO cycles that fluctuated 2-3 mg/L during low flow conditions (Figures 5-18 and 5-35). This station was located in a shallow riverine reach of the river and the DO measured during this study was consistent with the MADEP screening guidelines for rivers that include small diel changes in DO of < 3 mg/L and saturation <

125% (MADEP 2025). The data collected during this study suggest the inflow to the Project impoundment is sufficient for supporting uses based on DO criteria.

Four water quality monitoring stations were located within the Project impoundment (Stations LH-IM-01, LH-IM-02, LH-IM-03, and LH-IM-04), with instruments deployed at mid-depth positions, between 7 and 17 ft deep (increasing depth from upstream to downstream). At stations LH-IM-01, LH-IM-02, and LH-IM-03, DO concentration was measured consistently above the WQ standard of 5 mg/L, while at Station LH-IM-04 there were several exceedances of the 5 mg/L DO standard as measured at the 17 ft. depth at that station (Figures 5-19 through 5-22). Station LH-IM-01 had DO values and diel variations that were very similar to the upstream station LH-US-01, while the other three impoundment stations were characterized by highly variable DO conditions, likely related to the depth effects of flows through the impoundment. DO saturation was generally less than 125% at stations LH-IM-01, LH-IM-02, and LH-IM-04, while at station LH-IM-03 there were multiple instances of supersaturation above that level (Figures 5-36 through 5-39).

Three water quality monitoring stations were located on the main stem of the Merrimack River downstream of the Project dam including stations LH-DS-01, LH-DS-02, and LH-DS-03. DO concentrations measured at these stations were consistently above the 5 mg/L standard with one exception when a DO measurement of 4.76 mg/L was recorded at LH-DS-02 on August 18. Daily DO variations were low at the beginning of the study when inflow and spill over the dam were highest while DO became more variable at all three stations after June 26 with decreasing inflow and spill (Figures 5-25 through 5-27). Daily variations of 2-3 mg/L DO were typical under low flow conditions at the downstream stations and in the most extreme case was as high as 5 mg/L on August 17. DO saturation at the downstream stations varied between 70 and 140% (Figures 5-42 through 5-44) with mean daily averages of 97–104% for the full study period (Table 5-3). The tailrace station LH-TR-01 had patterns and values of DO that were comparable to the downstream stations (Figures 5-23 and 5-40) and under low inflow/spill conditions turbine outflows through the tailrace were the primary source of flow to the downstream stations during normal Project operations. No exceedances of the 5 mg/L DO standard were measured at the tailrace station and average DO saturation was approximately 105% for the duration of the study at LH-TR-01. Similar to the downstream stations, at the tailrace station daily DO variations of 2-3 mg/L were typical and DO saturation typically varied between 80 and 140%.

A single monitoring station was located in the river reach immediately downstream of Essex Dam (LH-BY-01) to document conditions below the dam and above the confluence with the tailrace. DO was highly variable in the river reach immediately downstream of Essex Dam, although generally above the 5 mg/L standard, with only 4 discrete exceedances of the standard (10 total 15-minute measurement points below 5 mg/L) with a minimum DO value of 4.11 mg/L (Table 5-3 and Figures 5-24 and 5-41). The monitoring station in the river reach immediately downstream of Essex Dam was heavily influenced by turbine outflows to the tailrace as evidenced by highly variable water levels that would rise and fall with turbine outflow. DO was highly variable over

short timeframes in the river reach immediately downstream of Essex Dam and daily variations of DO greater than 7 mg/L were documented, coinciding with DO saturation varying between 70 and 160 %. The rapid changes in DO are likely explained by the combination of changing water sources between turbine outflow and spill/leakage to the river reach immediately downstream of Essex Dam as well as the documented presence of large algae mats that developed in the river reach immediately downstream of Essex Dam (see photos in Appendix B), that have known effects on DO.

A total of four monitoring stations were established in the North and South Canals at positions near the canal inlets (LH-SC-01 and LH-NC-01) and near the outlets (LH-SC-02 and LH-NC-02). The South Canal was dewatered from the second half of June through all of July and therefore no water quality data were collected during that period. The North Canal had highly variable DO conditions (Table 5-3 and Figures 5-28, 5-29, 5-45, 5-46), with the inlet station LH-NC-01 showing large daily DO variations of up to 6 mg/L, although there were no exceedances of the 5 mg/L DO standard at that station. DO was also highly variable at LH-NC-02, with daily variations typically on the order of 2-3 mg/L during low flows and there were 3 exceedances of the 5 mg/l DO standard on August 2-4. DO saturation varied between 63 and 190% at LH-NC-01 and between 46 and 160% at LH-NC-02. In the South Canal, DO was also highly variable (Table 5-3 and Figures 5-30, 5-31, 5-47, 5-48) with daily variation of 1-2 mg/L under low flow conditions at LH-SC-02. There were no documented exceedances of the 5 mg/L DO standard in the South Canal and DO saturation at the inlet was measured at less than 125% at LH-SC-01 (with the exception of 4 measurements above 125%), while at the outlet DO saturation as high as 159% was measured at LH-SC-02.

Two monitoring stations were located in the Spicket River as this water body receives outflow from the North Canal, with one station above the confluence with the North Canal (LH-SR-01) and one station below the confluence with the North Canal and above the confluence with the Merrimack River (LH-SR-02). The Spicket River was characterized by highly variable water levels in 2025, with a prolonged period of low flow and low water levels after July 1 that affected site access and monitoring. At LH-SR-01 deployed logger monitoring became infeasible after July 1 due to low water levels and a lack of viable deployment options (site safety and vandalism potential further limited deployment options in this urbanized reach). Continuous logging was abandoned at LH-SR-01; however, recurring spot measurements continued with weekly site visits. Station LH-SR-02 was also affected by low water levels and the station had to be moved downstream and into a deeper channel area after July 1 (see Tables 4-1, 4-2, and Figure 4-4). DO was measured at consistently high levels in the Spicket River and there were no documented exceedances of the 5 mg/L DO standard during this study (Figures 5-32 and 5-33). Daily DO variations were generally minimal in the Spicket River, typically less than 2 mg/L at LH-SR-01 and less than 1 mg/L at LH-SR-02. There was a period of highly variable DO at LH-SR-02 from August 12-19 (see Figures 5-33 and 5-50), although this may have been a result of interference or fouling on the logger (QC checks passed, so there were no data flags). The Spicket River Station

below the North Canal discharge LH-SR-02 was characterized by comparatively stable DO with few spikes or extremes in the data record. Influence of the North Canal discharge did not appear to have an effect on DO at LH-SR-02 despite the North Canal discharge station LH-NC-02 being characterized by highly variable DO.

Table 5-3. Summary of Continuous Monitoring Dissolved Oxygen Concentration (mg/L)

5.1.3 pH

The objective of continuous pH monitoring was to collect baseline information on pH in and around the Project area and assess the effects of the Project on pH under a range of flow, temperature, and operating conditions. PH was monitored successfully at each of the 16 water quality monitoring stations for all or some portion of the study period, as summarized in Table 5-1, and included periods of variable flows, temperatures, and power generation. The results of the continuous pH monitoring are presented in Table 5-5 and Figures 5-52 through 5-67. PH was measured at variable levels among all stations and throughout the study period with multiple exceedances of the 8.3 SU water quality standard (discussed in Section 5.4) and only a single exceedance of the 6.5 SO pH standard. The pH loggers were affected by fouling and the presence of algae on and around the sensor which resulted in portions of the data record being reported as use code 4; the invalid data are presented in figures for informational purposes but are omitted from station statistics (see Table 5-6 for a summary of invalid data periods). PH varied from 6.43 to 9.80 SU among all stations during the study, with a global average pH value of about 7.1 SU. PH varied between stations and exhibited seasonal variations as well as short term trends and daily patterns that were associated with flow and algae effects.

Similar to water temperature and DO, pH was associated with flow conditions during the study, exhibiting relatively uniform pH among stations during the high flow period in June when flows exceeded 10,000 cfs in the Merrimack River, increasingly variable pH during the transition to low flows, and highly variable pH at low flows below 3,000 cfs (Figure 5-68). Runoff events that temporarily increased flows resulted in temporary periods of more uniform pH at all stations, e.g. the flow events on August 01 and September 24.

Above the Project dam, pH generally became more variable from upstream to downstream with consistent diel pH cycles at LH-US-01 and LH-IM-01 (Figures 5-52 and 5-53) and more variable pH patterns at LH-IM-02, LH-IM-03, and LH-IM-04 (Figures 5-54 through 5-56). Daily pH variations of 0.5 – 2.0 SU were seen in the upstream and impoundment stations, with somewhat less variation at LH-IM-04, likely explained in part by the 17 ft monitoring depth at that station. Below the dam, the greatest variability in pH and the greatest number of exceedances of the 8.3 SU pH standard were documented at LH-BY-01 in the river reach immediately downstream of Essex Dam (Figure 5-58). The documented presence of significant algae at this monitoring location likely explains the high values and variability in pH measured there. The tailrace station LH-TR-01 (Figure 5-57) had less pH variability than the station immediately downstream of Essex Dam and was similar to the downstream stations LH-DS-01, LH-DS-02, and LH-DS-03 (Figures 5-59, 5-60, and 5-61). The tailrace is the primary flow source to the downstream reach under low flows and typical operating conditions so it would be expected to have similar pH conditions (barring localized effects). There were fewer exceedances of the 8.3 SU pH standard progressing downstream from the tailrace through the downstream stations, which may be partially explained by the deeper instrument deployment depths at LH-DS-02 and LH-DS-03 compared to the tailrace and upper part of the reach.

In the North Canal and South Canal, pH was generally quite variable and was affected by shallow water and algae growth. There were multiple exceedances of the 8.3 SU pH standard at each of the four monitoring stations in the canals with the highest pH values and greatest number of exceedances at LH-SC-02 and LH-NC-01, with the fewest number of exceedances at LH-NC-01 (Figures 5-62 through 5-65). The Spicket River monitoring stations were characterized by more stable pH values compared to the Merrimack River and canal stations, with typical daily variations of less than 0.5 SU and infrequent periods of greater variability in excess of 1 SU. The Spicket River below the confluence with the North Canal (station LH-SR-02) had patterns and values of pH that were similar to LH-SR-01 above the confluence and differed from the North Canal outlet station (LH-NC-02) and therefore it appears that outflow from the canal did not have a pronounced effect on pH at that station.

Table 5-5. Summary of Continuous Monitoring of pH (SU)

Continuous Monitoring Station	pH (s.u.)			
	Min	Max	Mean	Median
LH-US-1	6.69	8.49	7.10	7.03
LH-IM-01	6.67	8.45	7.01	6.95

5.2 Vertical Profiles (Dissolved Oxygen and Water Temperature)

A total of 18 vertical profiles of temperature and DO were measured at the Project impoundment station LH-IM-04 as presented in Figures 5-69 and 5-70. The profile data were collected to characterize water quality at the impoundment deep spot and determine whether there was thermal/chemical stratification and therefore the potential for entrainment and discharge of low-DO bottom water through the Project turbines. Concurrent with vertical profiles and sample collection for laboratory analysis, Secchi disk depth measurements were made to characterize water clarity conditions, as summarized in Table 5-7.

Thermal stratification was uncommon during this study, while DO stratification was somewhat more pronounced. Temperatures were relatively uniform from top to bottom with the greatest variability in the upper 2 m of the water column (Figure 5-69). Greater top to bottom temperature differences were documented with warmer ambient water temperatures above 24 °C, and under those conditions there was typically a 1–2 °C temperature difference in the upper 2m of the water column and then relatively uniform temperatures from 2 m to the bottom at 11 m. There were two instances of more pronounced thermal stratification on August 11 and August 18 with top to bottom temperature differences of greater that 3.5 °C. In both instances inflow was relatively low, less than 1,500 cfs. Water temperatures during vertical profile measurements generally met the 28.3 °C temperature standard, except for July 29 and August 11, when temperatures in the upper 0.5 meter of the water column equaled or exceeded that value.

DO was more variable in the water column than temperature and there were instances of greater than 5 mg/L DO differences between the top and bottom of the water column (Figure 5-70). The most pronounced top to bottom DO differences were measured on August 11 with a top to bottom DO difference of 9.51 mg/L and on August 18, with a top to bottom DO difference of 11.05 mg/L. There were three vertical profiles in which DO was measured below the 5 mg/L standard, including August 18, August 25, and September 16 at depths greater than 5 m. During high flow conditions early in the study in June with cooler ambient water temperatures, DO concentrations were relatively uniform through the water column and indicate well mixed conditions.

Secchi disk depth measurements were completed on 18 separate dates as presented in Table 5-7. The MADEP 2024 Consolidated Assessment and Listing Methodology (CALM) (MADEP 2025) uses a Secchi disk depth screening criterion of 1.2 m (3.9 ft) for evaluating lakes and impoundments. Secchi disk depth measurements varied from 4 to 8 ft during this study which was greater than the screening criterion of 3.9 ft.

5.3 Laboratory Analysis (Nutrients, Chlorophyll-a, TSS, and True Color)

Sampling for laboratory analysis of chemical parameters was completed five times during the study with samples collected at the upstream station LH-US-01, at the impoundment stations LH-IM-02 and LH-IM-03, and at the downstream stations LH-DS-01 and LH-DS-03. The objective of the water sampling and analysis task was to characterize water chemistry conditions throughout different parts of the Project study area under various seasonal flow, temperature, and operating conditions as presented in Tables 5-8 through 5-12.

Nutrients including TP, TN, nitrate/nitrite, and total Kjeldahl nitrogen (TKN) were analyzed in samples collected at LH-US-01, LH-IM-02, and LH-IM-03 as presented in Tables 5-8 through 5-10. Phosphorus is typically the limiting nutrient in freshwater systems and MADEP uses screening criteria of 0.05 mg/L TP for rivers entering a lake/reservoir and 0.025 mg/L for lakes and impoundments (MADEP 2025). The median TP at the upstream station LH-US-01 was 0.041 mg/L, which was less than the screening criteria of 0.05 mg/L (Table 5-8). The median TP at stations LH-IM-02 and LH-IM-03 within the impoundment were 0.066 and 0.050 mg/L, respectively, which exceeded the screening criteria of 0.025 mg/L by a factor of 2. TN, nitrate/nitrite, and TKN are presented in Tables 5-8 through 5-10. TN varied from 0.99 at LH-US-01 to 1.6 mg/L at LH-IM-03 as a five-sample median value. MADEP does not have numerical screening criteria for nitrogen in freshwater systems; however, the U.S. Environmental Protection Agency (USEPA) guidance for the region lists a reference condition of 0.71 mg/L for TN in rivers and streams which can be used for evaluation of water quality. TN samples (5-sample median) exceeded the USEPA reference condition at each of the three monitoring stations.

Chlorophyll-a was measured concurrent with nutrient samples to evaluate water quality conditions above the Project dam. MADEP uses screening criteria of 16 µg/L phytoplankton chlorophyll-a to evaluate deep rivers, lakes, and impoundments (MADEP 2025). Chlorophyll-a was measured at 9.9 µg/L at LH-US-01, 18 µg/L at LH-IM-02, and 19 µg/L at LH-IM-03, as 5-sample median values. The two impoundment stations had chlorophyll-a values greater than the screening criteria while the upstream station was less than the screening criteria.

Water clarity was evaluated as true color, TSS, and turbidity at stations LH-US-01, LH-IM-03, LH-DS-01, and LH-DS-03 (Tables 5-8 5-10, 5-11, 5-12). True color varied from 12 PCU at LH-US-01 to 17 PCU at LH-IM-03 as 5-sample medians. TSS varied from 3.2 mg/L at LH-US-01 to 3.85 mg/L at LH-IM-03 as 5-sample medians. Turbidity varied from 1.16 NTU at LH-DS-03 to 1.9 NTU at LH-IM-03 as 5-sample medians. MADEP does not have numerical screening criteria for water clarity indicators; however, USEPA guidance for the region lists a reference condition of 3.04 NTU for turbidity in rivers and streams which can be used for evaluation of water quality. Turbidity samples (5-sample median) did not exceed the USEPA reference condition at any of the three monitoring stations.

5.4 Benthic Macroinvertebrates

Macroinvertebrate sampling was completed on August 20, 2025 at the station downstream of Essex Dam and on August 21 at the station upstream of Essex Dam, consistent with the study objective to evaluate the current macroinvertebrate community at locations upstream and downstream of the Project dam.

5.4.1 Upstream Macroinvertebrates

Macroinvertebrate Sampling

The upstream sampling reach was located approximately 8.7 miles upstream of Essex Dam at the upper extent of the impoundment (Figure 4-5). The lower portion of the 500-m reach was located immediately upstream of the Lowell Wastewater Treatment Plant (Figure 4-6). Three Combined Sewer Overflows (CSO) outfall locations and one Utility/Main Outfall for Lowell fall within the total upstream reach (USEPA 2019a). Tables 5-13, 5-14, and 5-15 present the surrounding land use, water quality and instream habitat as recorded at the time of sampling for the upstream benthic macroinvertebrate sampling reach. A photo-log showing images of each transect end point riparian zone and riverine conditions is presented in Appendix D.

In general, the surrounding land use was characterized primarily as industrial and residential, with estimated riparian zone width varying from 0 to 12 -m and some areas of shoreline displaying heavy armoring with rip-rap and, in one instance, a concrete retaining wall (Figure 5-71). Riparian vegetation consisted mostly of trees, shrubs and woody vines and had a range of low to medium coverage across the set of transects. Water temperatures during the August 21, 2025 sampling effort ranged from 23.7°C to 24.8°C with dissolved oxygen (percent saturation) ranging from 92 to 111%. pH ranged from a low of 6.49 to 7.63 SU while specific conductivity was 226–230 µs/cm. The dominant inorganic substrates along both north and south shorelines consisted of primarily boulder, cobble, and sand. Sediment deposits observed were primarily sand and algal mats observed on rocks and woody substrate. Rooted submerged aquatic vegetation coverage was generally low throughout the reach although occasionally comprising larger proportions of the available habitat.

Due to the rapid increase in water depth close to the riverbank, samples consisted mainly of available stream bank habitat. These samples were allocated proportionate to the available inorganic substrate, aquatic vegetation, or woody debris and snags observed in Table 5-15. If a habitat was not suitable for sampling (i.e. large areas of bedrock) samples were collected from the closest similar habitat (i.e. smaller boulder/cobble habitat).

Table 5-13. Surrounding Land Use and River Width Values Associated with Each Transect at the Upstream Macroinvertebrate Sampling Station, August 21, 2025

Transect	Date	Unique ID	Start Time	End Time	Bank	Surrounding Land Use	Estimated River Width (m)

Figure 5-71. Upstream reach shoreline and riparian zone variability, August 21st, 2025.

Macroinvertebrate Community

A cumulative total of 526 specimens were identified from the composite sample collected upstream of Essex Dam, representing 53 genus-level taxonomic classifications. The taxonomic listings of the macroinvertebrate sample collected at the Lawrence Project upstream sampling reach are provided in in Appendix E. EPT (Ephemeroptera [7], Plecoptera [0], and Trichoptera [10]) represented 17 of the 53 total taxa, comprising 32.1% of the total taxa richness. The dominant taxon identified in the sample was *Gammarus fasciatus*, which represented 28.7% of all individuals within the assemblage. Collector-gatherers comprised 45.8% of individuals in the upstream sample. Functional feeding group composition can reflect trophic structure (interaction, production and food source availability) and provide information on the balance of feeding strategies in benthic assemblages (Barbour et al. 1999).

The Shannon Diversity index (H') score of 2.81 indicates a trend towards diversity in the distribution of individuals within the community and limited dominance among taxa. The calculated Hilsenhoff Biotic Index (HBI) value for the upstream reach was 5.98, supporting a finding of "Fair" water quality in terms of organic pollution and nutrient enrichment (Hilsenhoff 1987) (Table 5-13).

Table 5-16. Summary of Macroinvertebrate Metrics for the Upstream Reach, August 21, 2025

Upstream Reach	
Metrics	**Values**
Taxa Richness	53
EPT Taxa Richness	17
Percent EPT Taxa	32.1%
Percent Dominant Taxon	28.7%
Dominant Taxon	*Gammarus fasciatus*
Hilsenhoff Biotic Index	5.98
Hilsenhoff Biotic Index Rating	Fair
Shannon Diversity (base e)	2.81
Percent Collector-Gatherer Individuals	45.8%

5.4.2 Downstream Macroinvertebrates

Macroinvertebrate Sampling

The downstream station was located approximately 1.0 miles downstream of Essex Dam and was bisected by the confluence of flows from the Spicket River and North Canal (Figure 5-72). Two CSO Outfall locations fall within the downstream reach (USEPA 2019b). Tables 5-17, 5-18, and 5-19 present the surrounding land use, water quality and instream habitat for each sampled reach. A photo-log showing images of each transect end point riparian zone and riverine conditions is presented in Appendix D.

Surrounding land use was primarily industrial and commercial, with estimated riparian zone width varying from 0 to 12 -m with some areas of the shoreline armored with rip-rap or consisting of sand (Figure 5-72). Riparian vegetation consisted mostly of trees, shrubs and woody vines and had a range of low to medium coverage. Sediment deposits were primarily sand, and algal mats were observed on rocks and along the shoreline. Discrete water quality measurements collected at each sample zone show water temperatures ranging from 22.9°C to 24.8°C with dissolved oxygen (percent saturation) ranging from 83 to 114%. The pH ranged from a low of 6.95 to 7.77 SU while specific conductivity was 303–485 µs/cm. In-river, sand was consistently present in all transects, comprising between 5 and 90% of the available benthic substrate, with coarser substrates (i.e. boulder, cobble, gravel) contributing substantially depending on the bank and transect. Aquatic vegetation, occurring as primarily rooted submerged plants, was recorded as present in 8 of 12 transects in varying density (ranging from 1-75% coverage within a sample zone) and woody debris and snags were present in 7 transects with coverage ranging from 10 to 20%.

Macroinvertebrate sampling was allocated based on the available habitat within the defined sample zone. Similar to the upstream station, due to the rapid increase in depth, samples consisted mainly of available stream bank sampling. These samples were generally allocated proportionate to the available inorganic substrate observed in Table 5-19. If a habitat was not suitable for sampling (i.e. large boulders) samples were collected from the closest similar habitat (i.e., smaller boulder/cobble habitat).

Table 5-17. General Characteristics Associated with Each Transect at the Downstream Macroinvertebrate Sampling Station, August 20, 2025

Figure 5-72. Downstream reach shoreline variability, August 20, 2025.

Macroinvertebrate Community

A cumulative total of 501 specimens were identified from the composite sample collected from the reach downstream of Essex Dam, representing 42 genus-level taxonomic classifications. The taxonomic listings of the macroinvertebrate sample collected at the Lawrence Project downstream sampling reach are provided in Appendix E. EPT (Ephemeroptera [2], Plecoptera [0], and Trichoptera [7]) represented 9 of the 42 total taxa, comprising 21.4% of total taxa richness. The dominant taxon identified in the sample was *Gammarus fasciatus*, which represented 38.3% of all individuals within the assemblage. Collector-gatherers comprised 58.3% of individuals in the downstream sample. The Shannon Diversity index (H') score of 2.45 indicates a trend towards balance in the distribution of individuals within the community and limited dominance among taxa. The calculated HBI value for the downstream reach was 6.42, supporting a finding of "Fair" water quality in terms of organic pollution and nutrient enrichment (Hilsenhoff 1987) (Table 5-20).

Table 5-20. Summary of macroinvertebrate metrics for the downstream reach, August 20th, 2025

Downstream Reach	
Metrics	**Values**
Taxa Richness	42
EPT Taxa Richness	9
Percent EPT Taxa	21.4%
Percent Dominant Taxon	38.3%
Dominant Taxon	*Gammarus fasciatus*
Hilsenhoff Biotic Index	6.42
Hilsenhoff Biotic Index Rating	Fair
Shannon Diversity (base e) (H')	2.45
Percent Collector-Gatherer Individuals	58.3%

5.4.3 Macroinvertebrate Summary

Macroinvertebrate samples were collected using the LR-BP methodology (Flotemersch et al. 2006) at reaches identified in consultation with Mass Wildlife and located at points upstream and downstream of Essex Dam. Sampling downstream of Essex Dam was completed on August 20, 2025 and sampling upstream of the dam was completed on August 21, 2025. Weather conditions were consistent throughout the two sampling days, with partly cloudy to cloudy conditions and intermediate periods of rain.

Land use at the downstream station was characterized as primarily industrial and commercial whereas the upstream station was characterized as primarily industrial and residential. Both sampling reaches had an estimated riparian zone width varying from 0 to 12 -m and had areas of shoreline armored with rock or concrete walls and rip-rap. Riparian vegetation consisted mostly of trees, shrubs and woody vines and had low to medium coverage at most transects across both sites. Overall, shoreline and riparian habitat was reflective of riverine reaches that have been altered by human activity. Sand substrate was present in varying percent coverage at all sampling zones downstream and only absent from one zone upstream. The coarse mineral substrates at the upstream zones were primarily boulder and cobble whereas downstream it was primarily smaller cobble and gravel. Aquatic vegetation, primarily in the form of rooted submerged plants, were present throughout the upstream and downstream reaches in varying degrees of percent coverage. Snags and woody debris represented generally between 10 and 20% of available habitat in 5 of 12 upstream sampling zones and 7 of the 12 downstream sampling zones.

The upstream sampling reach yielded 526 individuals representing 53 taxa, compared to 501 individuals and 42 taxa at the downstream sampling reach. EPT taxa represented 32.1% and 21.7% of the total taxa richness for BMI samples collected upstream and downstream of Essex Dam, respectively. The Shannon diversity index values were similar between the two stations (upstream = 2.81; downstream = 2.45), indicating a similar degree of dominance within taxa for both reaches.

The most abundant taxon, *Gammarus fasciatus*, was the same for each site comprising 28.7% of specimens upstream and 38.3% of specimens downstream. *Gammarus fasciatus* is an amphipod with moderate tolerance of nutrient enrichment and is a collector-gatherer, opportunistically feeding on available detritus or benthic debris. HBI values were 5.98 upstream and 6.42 downstream, both values supporting a finding of "fair" water quality in terms of nutrient input or organic pollution.

Table 5-21. Summary of Macroinvertebrate Metrics for the Downstream and Upstream Sampling Reaches

Metrics	Upstream Values	Downstream Values
Taxa Richness	53	42
EPT Taxa Richness	17	9
Percent EPT Taxa	32.1%	21.4%
Percent Dominant Taxon	28.7%	38.3%
Dominant Taxon	*Gammarus fasciatus*	*Gammarus fasciatus*
Hilsenhoff Biotic Index	5.98	6.42
Hilsenhoff Biotic Index Rating	Fair	Fair
Shannon Diversity (base e) (H')	2.81	2.45
Percent Collector-Gatherer Individuals	45.8%	58.3%

5.5 Water Quality Standards

The water quality study goals and objectives included collecting baseline water quality information to evaluate the Project area water resources within the framework of Massachusetts surface water quality standards (314 CMR 4.00[2]). The Merrimack River and Spicket River are the primary surface water bodies in the Project area and these are identified as Class B, warm water fisheries. Class B inland waters are designated as habitat for fish, other aquatic life, and wildlife, including for their reproduction, migration, growth and other critical functions, and for primary and secondary contact recreation. Class B waters shall be suitable for irrigation, agriculture, and industrial cooling and process uses. Class B water shall have consistently good aesthetic value. Water quality standards set forth for Massachusetts Class B warm waters include the following:

Dissolved Oxygen (DO):

> 314 CMR 4.05(3)(b)(1). Classes and Criteria, Inland Water Classes, Class B, Dissolved Oxygen. Dissolved Oxygen shall not be less than 5.0 mg/L. Where natural background conditions are lower, DO shall not be less than natural background conditions. Natural seasonal and daily variations that are necessary to protect existing and designated uses shall be maintained.

[2] https://www.epa.gov/system/files/documents/2023-06/mawqs-2023.pdf

Temperature:

> 314 CMR 4.05(3)(b)(2). Classes and Criteria, Inland Water Classes, Class B, Temperature. Temperature shall not exceed 83°F (28.3°C). The rise in temp due to discharge shall not exceed 5°F (2.8°C) in rivers and streams based on the minimum expected flow for the month.

pH:

> 314 CMR 4.05(3)(b)(3). Classes and Criteria, Inland Water Classes, Class B, pH. pH shall be in the range of 6.5 – 8.3 Standard Units (SU) and not more than 0.5 SU outside of the natural background range. There shall be no change from natural background conditions that would impair any use assigned to Class B.

Solids:

> 314 CMR 4.05(3)(b)(5). Classes and Criteria, Inland Water Classes, Class B, Solids. The waters shall be free from floating, suspended, and settleable solids in concentrations and combinations that would impair and use assigned to Class B that would cause aesthetically objectionable conditions, or impair the benthic biota or degrade the chemical composition of the bottom.

Color and Turbidity:

> 314 CMRP 4.05(3)(b)(6). Classes and Criteria, Inland Water Classes, Class B, Color and Turbidity. The waters shall be free from color and turbidity in concentrations or combinations that are aesthetically objectionable or would impair any use assigned to Class B.

Nutrients:

> 314 CMRP 4.05(5)(c). Unless naturally occurring, all surface waters shall be free from nutrients in concentrations that would cause or contribute to impairment of existing or designated uses and shall not exceed the site-specific criteria developed in a TMDL or as otherwise established by the Department pursuant to 314 CMR 4.00 including, but not limited to, those established in 314 CMR 4.06(6)(c): Table 28: Site-specific Criteria (there are no site-specific criteria for the Merrimack or Spicket Rivers).

5.6 Water Quality Exceedances

The water quality data collected during this study were compared to the Massachusetts surface water quality standards (314 CMR 4.00) presented in section 5.4 to assess water quality in the Project study area. Only numerical water quality standards were evaluated as narrative standards are interpretive and beyond the scope of this assessment. For the purposes of this assessment, an exceedance of a water quality standard is presented as any measurement(s) within a calendar day that does not meet a water quality standard (i.e., greater than or less than the threshold for evaluation). Discrete exceedances are presented for each station and day of measurement, as well as the cumulative duration of the exceedance (i.e. the total number of 15-minute interval measurements). Exceedances based on both continuous monitoring data and vertical profile

measurements are presented, although the duration of an exceedance for vertical profile measurements cannot be calculated as it is represented by a single reading.

The surface water temperature standard of 28.3 °C was exceeded 50 times during the study as presented in Table 5-13. Temperature exceedances occurred between June 24 and August 17 on 19 discrete dates and at 10 stations with a median 5.5-hour duration. The DO standard of 5 mg/L was exceeded 18 times during the study as presented in Table 5-14. DO exceedances occurred between July 31 and September 20 on 11 discrete dates and at 4 stations with a median 1.25-hour duration. The pH standard of <6.5 or >8.3 was exceeded 218 times during the study as presented in Table 5-15. Exceedances of the pH standards occurred between June 10 and September 25 on 65 discrete dates and at 14 stations with a median 5.6-hour duration.

Table 5-22. The Massachusetts Surface Water Quality Standards Daily Exceedances of Temperature (°C)

Exceedance no.	Station	Date	Duration (Hours)	Maximum Temp value (°C)

5.7 Additional Information

Between October 22-24, 2024 HDR, Engineering (HDR) conducted the Condition Assessment of Historic Properties and Associated Canal System. As per the SPD, HDR observed the North and South Canal walls for discharge points during the site visit. On October 22, 2024, HDR started walking from the Broadway Street bridge along the south wall of the South Canal, heading east. Photographs were taken periodically of the south wall of the South Canal using a GoPro camera on a telescopic rod, matching the pace of the camera operator. Once the end of the South Canal was reached, HDR walked back along the south wall, photographing the north wall until reaching the Broadway Street bridge. This was due to limited public access on the north wall. On October 23, 2024, HDR repeated the same procedure for the North Canal; however, HDR walked along the north wall of the North Canal, as there was limited public access along the south wall. On October 24, 2024, HDR was escorted by Essex operations staff as they photographed and observed the portions of both the North and South Canals upstream of the Broadway Street bridge.

During the site visit, no active discharges were identified. Minor seepage was observed at discharge locations, most likely caused by groundwater finding a path. See Figure 5-73 below. In discussions with Essex' operators and staff, they have never observed active discharges into the North and South canal. Additionally, local stakeholders at the Initial Study Report (ISR) in May 2025 opined that they have never seen active discharges into the canals. Appendix F provides a map of known (regulated) outfalls into the canals as part of the Municipal Separate Storm Sewer System (MS4) permitting system. Most, if not all of the canal-located stormwater outfalls appear to be owned by City of Lawrence (City of Lawrence 2024).

Figure 5-73. Minor seepage around discharge pipe, October 2024

6 Summary

Normandeau completed a water quality study for the Lawrence Hydroelectric Project (FERC No. 2800) from June 2, 2025 through October 1, 2025. The water quality study was completed in accordance with the RSP and with modifications based on agency communications. The completed study was successful in meeting the goals and objectives of the RSP that were to collect sufficient data to understand current water quality conditions at the Project, assess the designated uses for the three Assessment Units (MA84A-03, MA84A-04, MA84A-10) potentially affected by the Project, and assess any effects of Project operations on water quality in the affected Assessment Units. The study was comprised of continuous monitoring of DO, water temperature, and pH at 16 monitoring stations; weekly measurements of DO, water temperature, and pH as a vertical profile, as well as Secchi disk depth at the deepest known spot in the Project impoundment; collection of water samples for laboratory analysis of nutrients and chlorophyll-a at 3 monitoring stations upstream of the Project dam; and collection of water samples for laboratory analysis of turbidity, TSS, and true color a 4 monitoring stations above and below the Project dam; and collection and analysis of benthic macroinvertebrate samples above and below the dam.

Objective: Collect sufficient data to understand current water quality conditions at the Project.

The study was completed over a 4-month period that was characterized by a wide range of flow, temperature, and Project operating conditions. The study period included high flows with seasonably cool temperatures during much of the month of June when the region was at the end of a prolonged period of frequent precipitation and runoff that began in April. During this high flow period project operations included power generation at or near full capacity and high spill flow conditions. A change in the weather pattern at the end of June resulted in a prolonged drought period through the remainder of the study characterized by a long flow recession limb from earlier high flows with increasing water temperatures, then a prolonged low flow period with high temperatures, sporadic rain/runoff events, and a seasonal transition to early autumn conditions with low flows and cooling temperatures. Project operations during the low flow period included reduced power generation, including at minimum generation capacity, minimal spill, and cessation of fish lift flow in July. Thus, the project study period encompassed a wide range of flow, temperature, and operating conditions that represented both typical and atypical conditions that might be encountered in a summer season.

The 2025 field season presented an ideal study period, and the completed water quality study was successful in documenting water quality conditions within the full spatial extent of the Project area throughout the study period. 16 monitoring stations were utilized to document water quality above the influence of the Project in the Merrimack River, within the Project impoundment, below the Project, within 2 canals receiving diverted flows from the Project impoundment, within the Spicket River above and below the influence of canal flows, within the river reach immediately downstream of Essex Dam, and within the Project tailrace. Each of the 16 monitoring stations was visited weekly to ensure the deployed instruments were maintained frequently, operating correctly, and to minimize any data gaps that could result from equipment failure, loss, or vandalism. A total of 386,483 valid water quality measurements were collected from the continuous logging instruments during this study, supplemented by 18 vertical profile measurements, multiple spot measurements, QC measurements, 165 laboratory analyses of water chemistry, and collection and taxonomic analysis of two composite benthic macroinvertebrate samples. This study provides a highly comprehensive assessment of water quality conditions in and around the Project area collected during a field season that encompassed a wide range of flow, temperature, and operating conditions.

Objective: Assess the designated uses for the three Assessment Units (MA84A-03, MA84A-04, MA84A-10) potentially affected by the Project.

Designated uses for surface water Assessment Units in Massachusetts are identified in 314 CMR 4.00 Massachusetts Surface Water Quality Standards (SWQS) and sustained through attainment of the minimum water quality criteria prescribed in those regulations. This water quality study was successful in collecting a large amount of data to be assessed within the framework of the SWQS as presented above in Sections 5.4 and 5.5. During the study there were documented exceedances

of the SWQS for temperature, DO, and pH. Exceedances of the DO standard (5 mg/L), temperature standard (28.3 °C), and the lower pH standard (6.5 SU) were relatively uncommon and short-lived during the study (see Sections 5.1.1 and 5.1.2). Exceedances of the upper pH standard were frequently documented during the study, particularly during low flow/high temperature periods and especially in areas where algae growth was prevalent. The Merrimack River and Spicket River have listed impairments for TP and nutrients, respectively, in these Assessment Units. The nutrient data collected during this study are consistent with those impairments as measured TP concentrations exceeded MADEP impairment screening criteria (see Section 5.3). Nutrient impairment and associated excess algal growth would be expected to result in exaggerated diel pH and DO patterns, including high pH and DO supersaturation during daylight hours/peak photosynthesis, as were documented during this study.

Objective: Assess effects of Project operations on water quality in the affected Assessment Units.

The study design allowed for water quality data collection through the full extent of the Project area, including reaches of the Merrimack River and Spicket River upstream of the Project influence and therefore provides information helpful for assessing the effects of Project operations on water quality. A significant limitation to evaluating Project-specific effects is the combined effects of the developed watershed in the vicinity of the Project that includes a wastewater treatment facility discharge immediately upstream of the impoundment, MS4 discharges and CSO discharges from the urban areas of Lowell and Lawrence, Massachusetts and nonpoint pollution sources throughout the watershed.

Project influences on water quality include impoundment effects to the Merrimack River, variation in flow sources and pathways through the Project infrastructure (as spill, turbine flow, and flows through the upstream and downstream fish passage structures), flow diversions to the canals, and discharges from the canals to the Merrimack River and Spicket River.

Impoundment effects to the Merrimack River (MA84A-03) were documented as periodic occurrences of temperature and DO stratification/development of low DO water at lower depths of the impoundment (see Sections 5.1.2 and 5.2). Thermal and chemical stratification are known phenomena in impounded rivers, and it is unsurprising that stratification would develop in the Project impoundment. Stratification events were uncommon and transient with occurrences primarily during low flow/high temperature periods. While low DO bottom water did develop in the impoundment, there was no evidence that it was entrained into the Project intake and transmitted downstream (i.e. to MA84A-04) as the tailrace monitoring station did not have any documented exceedances of the 5 mg/L DO standard during this study and there was only one documented exceedance of the DO standard at any of the three downstream monitoring stations, in MA84A-04.

Variation in flow sources at the dam (including spill, turbine outflow, and diversion of flows to the canals and fish passage structures) influenced downstream water quality conditions at MA84A-04. The most pronounced effect was at the river reach immediately downstream of Essex Dam, where variations in turbine outflows to the tailrace were associated with changes in water level in the river reach immediately downstream of Essex Dam including periods of low water level and low flow through the "bypass" area. Low water levels in the river reach immediately downstream of Essex Dam were associated with accumulation of algae in this area which likely affected DO and pH, as evidenced by the pronounced diel pH and DO cycles at the monitoring station in the river reach immediately downstream of Essex Dam (see Sections 5.1.2 and 5.1.3). The monitoring stations in the downstream reach were also affected by variations in flow sources including a transition from spill over the dam as the primary flow source to outflow from the tailrace as the primary flow source . Temperature, DO, and pH were most stable under conditions where spill was the primary flow source to the downstream reach below the Project dam, However, temperature, DO, and pH were most stable at all monitoring stations under high flow conditions, so the effect of spill on downstream water quality is unlikely to be the most significant factor. Exceedances of temperature, DO, and the lower pH standards were uncommon downstream of the dam, regardless of operations. In contrast, there were multiple exceedances of the pH upper standard of 8.3. The high pH measurements in the downstream reach are consistent with measurements at the tailrace monitoring station and indicate this water quality condition likely results from upstream conditions passing through the turbines to the tailrace and downstream reach. Highly variable pH measurements and pH exceedances were also documented in the impoundment and, to a lesser extent, the upstream monitoring station and likely indicate a watershed pH issue related to the nutrient impairments in the watershed.

Water quality in the North and South Canals was directly affected by Project operations as flows to the canals are primarily controlled by diversions and/or leakage from the impoundment, estimated at 100 cfs combined between the two canals. Both canals were characterized by multiple exceedances of the upper pH water quality standard, and the North Canal also had exceedance of the temperature and DO standards. Water quality monitoring was limited in the South Canal due to the canal being dewatered for construction for multiple weeks during the summer. The elevated water temperatures measured in the North Canal were likely a result of the shallow water in the canal, which would be prone to more amplified daily temperature cycles compared to deeper water environments in the Project study area. The high pH values measured in the canals as well as the pronounced diel pH/DO cycles and high DO supersaturation values are all consistent with excess nutrient issues in the canals (which are a known impairment in the watershed) and heavy algal/plant growth (which were documented as persistent and extensive in the canals during this study).

The Project affects a reach of the Lower Spicket River (MA84A-10) and the Merrimack River below the Project dam (MA84A-04) at and below the North Canal and South Canal discharges, respectively. The Spicket River below the North Canal discharge did not have any exceedances of

the DO or lower pH water quality standards but did have several exceedances of the upper pH standard and the temperature standard. Data are limited from the Spicket River monitoring station above the North Canal discharge (due to low flows and logistical challenges for using deployed loggers), so it is difficult to make a direct comparison, yet the Spicket River below the North Canal has water quality that is comparable to or better than the other riverine monitoring stations utilized for this study. The South Canal discharges to the Merrimack River between two monitoring stations in the reach downstream of the dam (LH-DS-01 and LH-DS-02). Water quality was similar between downstream stations, with exceedances of the high pH standard at all three downstream monitoring stations and a single exceedance of the DO standard and two exceedances of the temperature standard below the South Canal discharge. Water quality at LH-DS-03, which was the lowermost station used in this study, can be used to characterize the aggregate downstream effects of Project operations. During the study, there were no exceedances of the DO or lower pH water quality standards at Station LH-DS-03, there were two exceedances of the temperature standard, and there were 7 exceedances of the upper pH standard. These results are similar to the upstream station, located above the Project influence, with the caveat of data gaps in water quality records at both stations.

While conclusive statements of the effects of Project operations on water quality are challenging, due to the urbanized watershed in which the Project is located, the data collected for this study indicate excess nutrients are the primary water quality issue in the Project area as evidenced by high nutrient values, documented excessive algal growth at multiple sites, exaggerated diel cycles of DO and pH, high pH and high DO supersaturation during daylight hours, as well as periodic episodes of temperature/DO stratification in the impoundment. Nutrient pollution is a known impairment in the watershed and is best addressed through a watershed approach to nutrient management. It is unlikely that Project operations can unilaterally be utilized to manage nutrient issues in the watershed or the immediate Project area.

7 Variances from the Approved Study Plan

The variances from the RSP are as follows:

- During vertical profiles, the final reading was measured 0.1 -m from the bottom rather than 1.0 -m.
- The South Canal was dewatered for a construction project from week two to week nine of the study. The data loggers at LH-SC-01 and LH-SC-02 were removed for the duration of the dewatering.
- The data loggers at LH-SR-01 were removed during week six of the study due to the low water level on the Spicket River. The river was no longer navigable via boat due to the water level and was not traversable by foot due to the injury risk posed by the amount of trash littering the riverbed. On days when the downstream loggers were downloaded, an instantaneous reading was collected with the YSI at LH-SR-01 first thing in the morning. This was repeated for the remainder of the study. The readings were collected from the

footbridge near the original station position. The water level remained low throughout the study period, so redeployment of data loggers was not feasible.

- Several stations were moved from their original locations during the study. LH-US-01 was moved several times over the course of the month of June to put distance between the station and the upstream riffle as recommended by MADEP. During week three, LH-DS-01 was moved due to anglers deflating the buoy with thirteen lures caught on the station at the time of recovery. The station was moved downstream, and when flows and angler presence decreased, it was moved back to its original location during week nine. During week five LH-SR-02 was moved downstream due to the low flows on the Spicket River where it remained through the rest of the study. LH-DS-03 was moved several feet closer to the left bank of the Merrimack River during week six as the water level on the river was low, and the original deployment spot was getting shallow. During week twelve, LH-TR-01 was moved from the right bay to the left bay at the tailrace, due to dam operations. The water quality loggers were still located in the tailrace flow.
